

Helsinki, 03 February 2021

**Addressees**

Registrant(s) of TOFA\_DimerFA\_TETA PAA as listed in the last Appendix of this decision

**Date of submission of the dossier subject to this decision**

19/09/2018

**Registered substance subject to this decision ("the Substance")**

Substance name: Fatty acids, C18-unsatd., dimers, oligomeric reaction products with tall-oil fatty acids and triethylenetetramine

EC number: 500-191-5

CAS number: 68082-29-1

**Decision number:** Please refer to the REACH-IT message which delivered this communication (in format CCH-D-XXXXXXXXXX-XX-XX/F)**DECISION ON A COMPLIANCE CHECK**Under Article 41 of Regulation (EC) No 1907/2006 (REACH), you must submit the information listed below, by the deadline of **8 August 2024**.

Requested information must be generated using the Substance unless otherwise specified.

**A. Information required from all the Registrants subject to Annex VII of REACH**

1. Water solubility (Annex VII, Section 7.7.; test method: EU A.6./OECD TG 105/OECD GD 29)
2. Short-term toxicity testing on aquatic invertebrates (Annex VII, Section 9.1.1.; test method: EU C.2./OECD TG 202)
3. Growth inhibition study aquatic plants (Annex VII, Section 9.1.2.; test method: [EU C.3./OECD TG 201)

**B. Information required from all the Registrants subject to Annex VIII of REACH**

1. Short-term toxicity testing on fish (Annex VIII, Section 9.1.3.; test method: OECD TG 203)
2. Simulation testing on ultimate degradation in surface water also requested below (triggered by Annex VIII, Section 9.2.)
3. Soil simulation testing also requested below (triggered by Annex VIII, Section 9.2.)
4. Sediment simulation testing also requested below (triggered by Annex VIII, Section 9.2.)
5. Identification of degradation products also requested below (triggered by Annex VIII, Section 9.2.)

6. Bioaccumulation in aquatic species also requested below (triggered by Annex I, Sections 0.6.1. and 4; Annex XIII, Section 2.1.)

**C. Information required from all the Registrants subject to Annex IX of REACH**

1. Long-term toxicity testing on aquatic invertebrates (Annex IX, Section 9.1.5.; test method: EU C.20./OECD TG 211)
2. Long-term toxicity testing on fish (Annex IX, Section 9.1.6.; test method: OECD TG 210)
3. Simulation testing on ultimate degradation in surface water (Annex IX, Section 9.2.1.2.; test method: EU C.25./OECD TG 309) at a temperature of 12 °C
4. Soil simulation testing (Annex IX, Section 9.2.1.3.; test method: EU C.23./OECD TG 307) at a temperature of 12 °C
5. Sediment simulation testing (Annex IX, Section 9.2.1.4.; test method: EU C.24./OECD TG 308) at a temperature of 12 °C
6. Identification of degradation products (Annex IX, 9.2.3.; test method: using an appropriate test method)
7. Bioaccumulation in aquatic species (Annex IX, Section 9.3.2; test method: OECD TG 305)

Reasons for the request(s) are explained in the following appendices:

- Appendices entitled "Reasons to request information required under Annexes VII to IX of REACH", respectively.

**Information required depends on your tonnage band**

You must provide the information listed above for all REACH Annexes applicable to you, and in accordance with Articles 10(a) and 12(1) of REACH:

- the information specified in Annexes VII and VIII to REACH, for registration at 10-100 tpa;
- the information specified in Annexes VII, VIII and IX to REACH, for registration at 100-1000 tpa;
- the information specified in Annexes VII to X to REACH, for registration at more than 1000 tpa.

You are only required to share the costs of information that you must submit to fulfil your information requirements.

For certain endpoints, ECHA requests the same study from registrants at different tonnages. In such cases, only the reasoning why the information is required at lower tonnages is provided in the corresponding Appendices. For the tonnage where the study is a standard information requirement, the full reasoning for the request including study design is given. Only one study is to be conducted; the registrants concerned must make every effort to reach an agreement as to who is to carry out the study on behalf of the other registrants under Article 53 of REACH.

### **How to comply with your information requirements**

To comply with your information requirements you must submit the information requested by this decision in an updated registration dossier by the deadline indicated above. You must also update the chemical safety report, where relevant, including any changes to classification and labelling, based on the newly generated information.

You must follow the general testing and reporting requirements provided under the Appendix entitled "Requirements to fulfil when conducting and reporting new tests for REACH purposes". In addition, you should follow the general recommendations provided under the Appendix entitled "General recommendations when conducting and reporting new tests for REACH purposes". For references used in this decision, please consult the Appendix entitled "List of references".

The studies relating to biodegradation and bioaccumulation are necessary for the PBT assessment. However, to determine the testing needed to reach the conclusion on the persistency and bioaccumulation of the Substance you should consider the sequence in which these tests are performed and other conditions described in Appendix entitled "Requirements to fulfil when conducting and reporting new tests for REACH purposes".

### **Appeal**

This decision, when adopted under Article 51 of REACH, may be appealed to the Board of Appeal of ECHA within three months of its notification to you. Please refer to <http://echa.europa.eu/regulations/appeals> for further information.

### **Failure to comply**

If you do not comply with the information required by this decision by the deadline indicated above, ECHA will notify the enforcement authorities of your Member State.

Authorised<sup>1</sup> under the authority of Christel Schilliger-Musset, Director of Hazard Assessment

---

<sup>1</sup> As this is an electronic document, it is not physically signed. This communication has been approved according to ECHA's internal decision-approval process.

## Appendix A: Reasons to request information required under Annex VII of REACH

### 1. Water solubility

Water solubility is a standard information requirement in Annex VII to REACH.

You have adapted this information requirement by providing

1. a statement indicating that it is not possible to test your substance experimentally,
2. predicted water solubility values, and
3. a value for critical micelle concentration (CMC) conducted on an analogue substance TOFA\_DimerFA\_TEPAA\_PAA (EC 500-289-8).

We have assessed this information and identified the following issues:

You have not claimed concrete adaptations. However, from your reasoning ECHA understands that you invoke adaptations of Annex XI, Section 2, Annex XI, Section 1.3. and Annex XI, Section 1.5. of REACH.

1. According to Annex XI, Section 2, testing may be omitted, if it is technically not possible to conduct the study as a consequence of the properties of the substance, e.g. if the substance is volatile, highly reactive or unstable, reactive in water or radioactive.

You provided the following statement: *"The test substance is a UVCB substance. It is therefore not possible to experimentally determine the water solubility."*

The mere fact that a substance is a UVCB substance is not a valid adaptation under Annex XI, Section 2. You have not substantiated why an experimental test is not possible for your Substance. Specifically, you have not provided evidence of attempts to determine the water solubility experimentally for your Substance.

In your comments to the draft decision you maintain that it is not technically feasible to determine the water solubility of the Substance due to its properties (*"UVCB, surface activity and hydrophobic properties"*). The UVCB issue has been already explained above. You further state that OECD 105 is only designed to determine the water solubility of pure substances and not of UVCBs, such as your Substance. However, as stated in Guidance R.7a Table R.7.1-5 the flask method, one of the methods available in the OECD 105, is suitable for complex substances, like your Substance. The additional arguments you provided in your comments, Substance being surface active and hydrophobic, are not in isolation valid adaptations under Annex XI, Section 2. You still have not substantiated why an experimental test is not possible for your Substance. Specifically, you have not provided evidence of attempts to determine the water solubility experimentally for your Substance.

Therefore, your adaptation is rejected.

2. Annex XI, Section 1.3. states that results obtained from valid QSAR models may be used instead of testing when the following cumulative conditions are met, in particular:
  - the substance falls within the applicability domain of the QSAR model;
  - adequate and reliable documentation of the applied method is provided; and
  - the results are adequate for classification and labelling and/or risk assessment.

According to ECHA's Practical guide "How to use and report (Q)SARs", section 3.4, a QSAR Model Reporting Format (QMRF) and a QSAR Prediction Reporting Format (QPRF) are

required to verify that the Substance falls within the applicability domain of the model, and to assess the adequacy of the prediction for the purposes of classification and labelling.

To consider the water solubility information adequate for REACH purposes, among others, the information must cover all the relevant structures of the Substance, especially in the case of a UVCB substance.<sup>2</sup> Further, to consider the substance to fall within the applicability domain of the model, among others, the model must predict well substances that are similar to the substance<sup>3</sup>.

You provided calculated values from EPISuite software for the "representative component", namely C16 derivative of TOFA DimerFA TETA PAA. You justify the selection of the representative components based on a) "It is the main target substance that the reaction was intended to produce"; and b) "It was expected to be the major component of the mixture". You report estimated water solubility values of 6.1 mg/l (WSKOW module) and  $1.6 \times 10^{-4}$  mg/l (WATERNT module) for your Substance based on the predictions for the "representative component".

Under "Any other information on results incl. tables", you state that "Before the EPISuite program was used to estimate the water solubility of the test substance, the validity of the program's calculations was evaluated by comparing the calculated vapour pressure for several related substances with known measured values." We understand that in this sentence you mean "water solubility" and not "vapour pressure". You provide the comparison in Table 1 in the IUCLID dossier. You further state that "The correlation between the calculated and measured values is considered good and acceptable for the purposes of this report."

We have assessed this information and identified the following deficiencies:

A. You have not provided any documentation for the QSAR prediction. In particular, you have not included a QMRF and/or a QPRF in your technical dossier. You have not reported the molecular structure (e.g. SMILES code) used for the prediction. However, based on the information in the technical dossier, ECHA can conclude on the applicability and adequacy of the prediction, as explained below.

B. Regarding the applicability domain of the model, Table 1 in the IUCLID dossier, Section 4.8, shows that the predicted values for related substances and fragments of the Substance are either significantly lower than the corresponding measured water solubility values (for oleic acid and fatty acids) or show high solubility of the substances (for DETA and TEPA). You did not justify why you consider this correlation as good. In absence of such justification or further documentation, ECHA considers the structure you used for your prediction outside the applicability domain of the model.

C. You have predicted the water solubility value for a single structure. A single structure, even if fulfilling the requirements under Annex XI, Section 1.3. for a QSAR prediction, is not adequate to cover the water solubility endpoint of a UVCB substance.

In your comments to the draft decision you acknowledge that the QSAR prediction for water solubility provided in the dossier is not adequate. You propose to use the OECD QSAR toolbox to run a prediction based on multiple constituents that you deem most

<sup>2</sup> OECD GD 23, p. 11.

<sup>3</sup> ECHA Guidance, Chapter [R.6: QSARs and grouping of chemicals](#).

representative of the UVCB Substance. You further propose to conduct QSAR prediction on the chemical moieties with molecular weights below or equal to 600 DA.

It is unclear what models and methods you propose to use for predicting the water solubility. You mention the QSAR Toolbox and "category reports", which indicates that you plan to use the Category approach in the Toolbox. Please note that category approach predictions with analogues are considered read-across, rather than QSAR, and would have to follow the rules specified under Annex XI, section 1.5.

You generically mention QSARs without specifying the models you intend to use. If you plan to use the Episuite WSKOW and WATERNT models please be aware that they are likely to be partly unsuitable for your Substance. The input structures are large, which means that the larger structures would be outside of the parametric and structural domain of both models.

Furthermore, as explained above, the information must cover all the relevant structures of the Substance, especially in the case of a UVCB substance. You propose to provide predictions only for those constituents that you deem are the most representative of the UVCB Substance, i.e. those constituents with molecular weight below or equal 600 DA. However, ECHA notes that the Substance contains several constituents above 600 DA (*"the Substance is a UVCB substance containing at least 16 components ranging in molecular weights from 146.15 to 1417.37 Da"*). Therefore, the selection of constituents you proposed for the QSAR predictions would not cover the whole UVCB Substance.

Since you have not provided in your comments any new predictions addressing the information requirement other than describing your intentions, the data gap remains.

Therefore, your adaptation is rejected.

3. Annex XI, Section 1.5. specifies two conditions which must be fulfilled whenever a read-across approach is used. Firstly, there needs to be structural similarity between substances which results in a likelihood that the substances have similar physicochemical, toxicological and ecotoxicological properties so that the substances may be considered as a group or category (addressed under 'Scope of the grouping'). Secondly, it is required that the relevant properties of a substance within the group may be predicted from data for reference substance(s) within the group (addressed under 'Assessment of prediction(s)').

Additional information on what is necessary when justifying a read-across approach can be found in the ECHA Guidance R.6 and related documents.

You have provided a CMC value based on a study conducted with another substance than your Substance. You justify the selection of this analogue substance based on slightly higher hydrophilicity of TEPA (tetraethylenepentamine) compared to TETA (triethylenetetramine, present in the Substance), and higher amount of monomeric fatty acids resulting in higher relative amount of adducts with lower MW. ECHA understands that you justify the selection of the source substance to be more water soluble than the Substance, i.e. apply a "worst case scenario".

We have assessed this information and identified the following issues:

#### *Adequacy and reliability of source studies*

According to Annex XI, Section 1.5., if the grouping concept is applied then in all cases the results to be read across must:

- be adequate for the purpose of classification and labelling and/or risk assessment;
- have adequate and reliable coverage of the key parameters addressed in the corresponding test method referred to in Article 13(3)

Specifically, you have provided a CMC value of 60 mg/l (corrected for amine 54 mg/l) conducted with an analogue substance "TOFA\_DimerFA\_TEPAA" in a surface tension study. The provided surface tension study indicates surface tension values between ~64 and ~69 mN/m for the analogue substance test material concentrations between 150.7 mg/l and 30.14 mg/l, respectively.

You estimated a value of 40 mg/l for water solubility of your Substance based on the QSAR predictions above and the CMC of an analogue substance.

The experimentally measured surface tension values for the analogue substance are above the limit value of 60 mN/m indicated in the EU Test method A.5 for surface active substances. Therefore, you have not demonstrated that a CMC value is a reliable estimate of the water solubility value for such substances and for your Substance. For these reasons, the surface tension study conducted with the analogue substance is not adequate for predicting the water solubility of the Substance.

Moreover, you have not explained how you concluded on a water solubility value of 40 mg/l based on the CMC value of 54 mg/l and predicted water solubility values of 6.1 mg/l (WSKOW module) and  $1.6 \times 10^{-4}$  mg/l (WATERNT module).

Therefore, your adaptation is rejected.

## 2. Short-term toxicity testing on aquatic invertebrates

Short-term toxicity testing on aquatic invertebrates is an information requirement under Annex VII to REACH (Section 9.1.1.).

You have provided the following information in the dossier:

- i. [REDACTED] 2013, key study, according to OECD TG 202 with the Substance;

Furthermore, in your comments to the draft decision you have provided the following information:

- ii. an adaptation under Annex VII, Section 9.1.1., Column 2 with the following justification: "*aquatic toxicity is unlikely to occur due to very low water solubility and unlikelihood to cross biological membranes*".

We have assessed this information and identified the following issues:

### i) Experimental study

A. To be adequate for the purpose of classification and labelling and/or risk assessment of the Substance, the study must be conducted in accordance with the applicable OECD test guidelines or other internationally recognised test methods (Article 13(3) of REACH). For the purpose of classification and labelling, as set out in the CLP Regulation, the study must provide information on intrinsic properties i.e. the basic properties of a substance or mixture as determined in standard tests or by other means designed to identify hazards. This is to be derived without consideration of exposure under realistic environmental

conditions<sup>4</sup>. As a consequence of the above, studies performed with modification to standard tests procedures impacting exposure cannot be considered relevant to derive intrinsic properties.

To fulfil the information requirement, a study must comply with OECD TG 202 and the requirements of OECD GD 23 (ENV/JM/MONO(2000)6/REV1) if the substance is difficult to test (Article 13(3) of REACH). Therefore, the following requirements must be met:

- the test medium fulfils the following condition(s): total organic carbon (TOC)  $\leq$  2 mg/L;
- use of a reliable analytical method for the quantification of the test material in the test solutions with reported specificity, recovery efficiency, precision, limits of determination (i.e. detection and quantification) and working range, when available; alternatively, a justification why the analytical monitoring of exposure concentrations is not technically feasible must be provided. For this purpose, a sufficiently sensitive analytical method must be used for the analysis of the test chemical in the test solutions or a statement from an analytical chemist must be provided to justify why lower detection limits (LOD) were not feasible (any preliminary analytical efforts should also be described in the report);
- the effect values can only be based on nominal or measured initial concentration if evidence is provided that the concentration of the test material has been satisfactorily maintained within 20 % of the nominal or measured initial concentration throughout the test (see also ECHA Guidance R.7b, Section R.7.8.4.1).

The Substance is UVCB, highly adsorptive (the estimated log K<sub>oc</sub> ranges from 6.5 to 8.6) and based on structural formula it indicates some surface active properties.

Your registration dossier provides an OECD TG 202 study showing the following:

- The test medium used was natural river water with the following characteristics: DOC of 2.98 mg/L and suspended matter of 13.4 mg/L was used as the test media. You provide the following justification for the deviation from standard medium: *"TOFA\_DimerFA\_TETA\_PAA has low water solubility and may sorb to organic and inorganic materials by different mechanisms. Due to these properties the test item was difficult to test in artificial water (e.g. sorption to the test organism and walls of the test vessel). Natural river water contains particulate as well as dissolved organic carbon to which the test item can sorb partially preventing that the test item settles onto surfaces. The sorbed fraction of the test item was difficult to extract from the test system which normally leads to low analytical recoveries. Nevertheless the test item was present in the test system and therefore available for exposure (dissolved in water and sorbed).*
- Analytical monitoring of exposure concentrations was not performed. You provide the following justification: *No determination of the test item concentrations was carried out. Preliminary investigations (non GLP) including the use of different analytical techniques showed that no specific method was available that meets the required sensitivity in the range of the test concentrations.* Moreover you summarised the methods you tried to use: the photometric method (limit of quantification of 1.6 mg/L, 230 nm wavelength), the evaporative light scattering detection (ELSD) (limit of detection above 10 mg/L) and the liquid chromatography with electrospray ionisation in positive mode (LC-ESI-MS).
- Effect values were based on nominal concentrations and you have not provided any evidence that the exposure concentrations have been maintained for the test substance during the study period.

The Substance is difficult to test due to the adsorptive and potentially surface active properties as explained above.

<sup>4</sup> CLP Guidance, Section 1.1.3.

Moreover, the study has the following deviations from the requirements of OECD TG 202 and OECD GD 23:

- The study was conducted with non-standard test media (natural water) with TOC above 2 mg/L, hence it does not meet the specifications given in OECD TG 202. The test substance is highly adsorptive and is therefore expected to bind to dissolved organic matter and particulate matter. Since river water differs from standard media with regards to the content of higher organic matter and particulate matter, the use of this modified test medium impacts the exposure to the test substance and decreases bioavailability of the substance. As a consequence the study does not inform on the intrinsic properties of the Substance hence the modification of the test media is not acceptable.

In your comments to the draft decision you consider that the studies currently in the dossier conducted with modified test media "show low potential for acute toxicity in a realistic environment and are scientifically acceptable". You consider the study is sufficient to facilitate hazard identification and risk characterisation but at the same time you acknowledge that for the purpose of classification and labelling, studies must provide information on the intrinsic properties without consideration of exposure under realistic environmental conditions.

As explained above, studies conducted in natural media cannot be accepted to fulfil this standard information requirement. You have not brought any new argumentation with this comments. Moreover, you do not explain why you consider it fine to submit data that cannot be used to fulfil all of the regulatory requirements identified above in this decision.

- Regarding your justification for not performing any determination of the test item concentrations, it is not acceptable for the following reasons:  
You summarise the three methods you tried to use.
  - Regarding the photometric method (limit of quantification of 1.6 mg/L, 230 nm wavelength), you indicate that it does not guarantee the required sensitivity. ECHA agrees that this method is not sufficiently sensitive, since it is well known that photometric measurements are not suitable to achieve low detection levels as it is required and in addition, it suffers of many interferences and a wavelength of 230 nm does not provide any selectivity.
  - Regarding the evaporative light scattering detection (ELSD) (limit of detection above 10 mg/L), you indicate that it does not guarantee the required sensitivity. ECHA agrees that this method is not sufficiently sensitive, and does not allow determination of the test item concentrations at adequately low detection level.
  - Regarding the liquid chromatography with electrospray ionisation in positive mode (LC-ESI-MS), you explained that it was not suitable because only the minor fractions were detectable. ECHA notes that the detection method (ESI-MS) can provide sensitivity and selectivity superior to the other 2 other detection methods explained above (i.e. photometric method and ELSD). However, ECHA does not agree with your claim that LC-ESI-MS is unsuitable, since the number of applicable MS techniques with Liquid Chromatography are multiple and very suitable for higher molecular weight above 2000/3000 Daltons as the heavier fractions of your substance. It is also possible to apply different LC-MS strategies to detect and quantify fractions with lower molecular weight and with high molecular weight by multiple analyses of the same sample.

You have not explained nor justified why you have not attempted different strategies to quantify the constituents of your Substance. Therefore, you have not demonstrated that you have applied the most appropriate techniques to ensure that the system is adequately monitored and results are documented.

In your comments to the draft decision you further explain that developing a sufficiently sensitive method is not technically feasible due to the substance properties. You highlight

that the Substance is a highly adsorptive UVCB, and based on structural formula it indicates some surface-active properties, making it difficult to analyse and that the attempts to develop the method to monitor the exposure concentrations during the test were not successful. You repeat the statement that "*Preliminary investigations (non GLP) including the use of different analytical techniques showed that no specific method was available that meets the required sensitivity in the range of the test concentrations.*" Finally you again discuss the detection limits of the three methods you tried to use (photometric and evaporative light scattering detection (ELSD) methods and the liquid chromatography with electrospray ionisation in positive mode (LC-ESI-MS)).

The justification provided in the comments is not acceptable, as explained in the following.

Regarding the discussed methods, you state that: "*ECHA has acknowledged that photometric and evaporative light scattering detection (ELSD) methods were not sensitive enough for the low detection levels necessary.*" ECHA notes that it has not excluded any detection technique "a priori" but only acknowledged recognised differences in the detection level among the different detectors: however, a method detection level shall be considered within the entire analytical protocol including extraction, purification, concentration, isolation, detection and quantification to fully judge the applicability and suitability of a method and not only by comparing values of the final detection phase.

Therefore, in your assessment of the suitable analytical methods you are lacking the evaluation covering of all the steps: the extraction, cleaning, detection and quantification protocols. Different final detection techniques could be used on different aliquots of the same sample to handle detection issues related to the molecular weight and structures of different fractions of the Substance.

In addition, your comment that "*liquid chromatography with electrospray ionisation in positive mode (LC-ESI-MS) was not suitable because only the minor fractions were detectable*" is unclear as the number of applicable MS techniques with Liquid Chromatography are known to be suitable for molecular weight above 2000/3000 Daltons. It is also possible to apply different LC-MS techniques to detect and quantify fractions with lower and higher molecular weights by multiple analyses of the same sample.

In conclusion, the statements provided by you are not acceptable since you do not explain in detail the analytical methodologies investigated and the issues encountered in the various steps, and you do not include the results achieved with specificity, recovery efficiency, precision, limits of determination (i.e. detection and quantification) that would potentially enable you to justify why the analytical monitoring of the exposure concentrations is not technically feasible.

- Since the test substance is highly adsorptive, it is expected that considerable losses will occur during the exposure period. In the absence of analytical monitoring of exposure concentrations, you have not demonstrate that the test substance concentration during the test was maintained within the required 20% of nominal concentrations.

Thus, the requirements listed above are not met and therefore the study is not adequate for the purpose of classification and labelling and/or risk assessment.

B. To comply with this information requirement, the test material in a study must be representative for the Substance (Article 10 and Recital 19 of REACH; ECHA Guidance R.4.1). Therefore, the unambiguous characterization of the composition of the test material is required to assess whether the test material is representative for the Substance.

The information on the composition of the test materials, provided in your dossier is limited in general to the numerical identifier and it does not contain information on the identity and quantitative occurrence of its constituents (groups of). More specifically for the test materials you did not report any other information relevant to identify the tested material and concentration levels of the groups of constituents present in the composition of the test material, such as a specific and detailed description of the manufacturing process (including reactants, ratio of starting material, temperature etc).

The test material composition is not sufficiently characterised, since identity and quantitative occurrence of the constituents is not provided. Therefore, this information is not sufficient to demonstrate that the test material is representative for the Substance.

ii) Column 2 adaptation:

Under Section 9.1.1., Column 2, first indent, Annex VII to REACH, the study may be omitted if aquatic toxicity is unlikely, for instance if the Substance is highly insoluble in water. ECHA Guidance R.7.8.5 explains that there is no scientific basis to define a cut off limit for solubility below which toxicity is unlikely. Therefore, the justification must demonstrate very low water solubility and low likelihood to cross biological membranes. For the latter, the indicators used for low likelihood of a high bioaccumulation potential (ECHA Guidance R.11, Figure R.11-4) must be considered, including:

- physico-chemical indicators of hindered uptake, and
- supporting experimental evidence of hindered uptake (no chronic toxicity for mammals and birds, no chronic ecotoxicity, no uptake in mammalian toxicokinetic studies, very low uptake after chronic exposure).

To conclude, provided justification cannot rely solely on physico-chemical properties of the substance and must be further supported by lack of adsorption and effect in toxicological/ecotoxicological studies. Unless it can reliably be demonstrated that aquatic toxicity is unlikely to occur, the Substance must be considered as poorly water soluble.

In your comments to the draft decision you provide:

- a conclusion of low likelihood to cross biological membranes substantiated with the following physico-chemical indicators: "the predicted Koc values vary from 6.5 to 8.6"

Your registration dossier provides:

- an estimated value of 40 mg/l for water solubility of your Substance based on the QSAR predictions and the CMC of an analogue substance (addressed under Section A.1);
- short-term toxicity studies in aquatic invertebrates and fish and algae growth inhibition study.

However, there is currently no reliable information on water solubility of the Substance (Appendix A.1). Moreover, regarding unlikelihood to cross biological membranes as explained above physico-chemical parameters (log Koc) value on its own cannot be used to assess this property. Furthermore, even if the aquatic toxicity studies provided in the dossier are not reliable (as addressed under A.2, A.3 and B.1), effects are observed indicating systemic exposure. Therefore, you have not demonstrated that toxicity is unlikely to occur and your adaptation is rejected.

In your comments to the draft decision, you agree to conduct a new study with the Substance if the information provided in the comments would not address the deficiencies of the current study.

As explained above, the information provided in the dossier and in the comments to the draft decision is not acceptable. Hence, the data gap remains.

You stated in your comments that if the test needs to be repeated, you 1) propose to conduct a further OECD 202 test using (i) synthetic test media, (ii) semi-static test design with 24h renewal of test media and without analytical determination and 2) you indicate that *"the Registrants would need to know which substance should be selected by the Registrants and would possibly be accepted by ECHA as Test Material"*.

We have assessed your comment and identified the following issue(s):

1) OECD TG 202 specifies that, for difficult to test substances, you must consider the approach described in OECD GD 23 or other approaches, if more appropriate for your substance. In all cases, the approach selected must be justified and documented. Therefore, the following requirements must be met (among others):

- the test medium fulfils the following condition(s): particulate matter  $\leq 20$  mg/L, total organic carbon (TOC)  $\leq 2$  mg/L, hardness between 140 and 250 mg/L (as CaCO<sub>3</sub>), pH between 6 and 9;
- the selection of the exposure system to be used in a tests should be guided by the time course of the experiment, the study design, the test species used, the characteristics (e.g. physicochemical properties) of the test chemical, and/or the results of a preliminary stability study.
- the concentrations of the test material are measured at least at the highest and lowest test concentration, at the beginning and end of the test;
- due to the properties of a Substance, it may be difficult to achieve and maintain desired exposure concentrations. Therefore, you must monitor the test concentration(s) of the Substance throughout the exposure duration and report the results. If it is not possible to demonstrate the stability of exposure concentrations (i.e. measured concentration(s) not within 80-120% of the nominal concentration(s)), you must express the effect concentration based on measured values as described in OECD TG 202.

You have not provided any detailed information on the test conditions listed above. E.g. you have not specified what is a composition of the syntetic test media and therefore it is not possible for ECHA to assess if a new test, as described by you in your comment, will provide information on intrinsic properties of the substance. In addition, it needs to be demonstrated that with the selected route/type of exposure the concentration of the test material is maintained through out the test.

Finally, your comment: *"Based on the registrant's extensive knowledge of the molecules we highlight that the sensitivity of the analytical cannot be improved and therefore if a repeat OECD 202 study is conducted, ECHA should be aware that analytical sensitivity will not be improved"* would need to be substantiated with data and scientifically valid justification.

2) In the general comments you stated that: *"the Substance is a UVCB substance containing at least 25 components ranging in molecular weights from 143.15 to 1453.39 Da. (see detailed Report of Lead registrant). Each individual component varies in unknown concentrations within the registered UVCB substance"*. Moreover you state that: *"This significant compositional variation is the reason why analytical confirmation during aquatic testing is not possible, no specific moiety can be used for analytical determination in any of the requested simulation or bioaccumulation tests"*. Finally you stated: *"the Registrants would need to know which substance should be selected by the Registrants and would possibly be accepted by ECHA as Test Material"*.

As explained above under point B, unambiguous characterization of the composition of a test material is required to assess whether a test material is representative for the Substance.

Moreover according to the ECHA Guidance R.11, the following assessment approaches could be considered for UVCB substances: "known constituents" approach, "fraction profiling" (or "block profiling") approach, The whole substance approach, or any combination of these approaches.

If you decide to use the fraction profiling or known constituent approach, as described in ECHA Guidance R.11, in your robust study summary you need to sufficiently justify the reasons for selection of the relevant fraction/constituent and explain why testing of this selected fraction/constituent would be appropriate to fulfil the purposes of the chemical safety assessment (PBT assessment, or risk characterization, classification) of the registered substance as a whole.

According to ECHA Guidance R.11 for the purpose of the PBT/vPvB assessment "Known constituents" approach *"can be applied when a substance is 'a priori' known to contain specific constituents at relevant concentrations, these constituents are suspected based on available information to represent the worst case of the (v)P, (v)B and T properties of all constituents of the substance, and these specific constituents can be isolated or separately manufactured or otherwise acquired for the purpose of testing."*

The worst-case constituent(s) are to be predicted in regards of the property under consideration (e.g. aquatic toxicity or degradability or bioaccumulation). Intrinsic property is not dependent on the quantity/concentration of the constituent in the fraction or substance. Instead, the selection of the most (suspected) constituent must consider, e.g. the carbon chain length, molecular weight, type of bonds present in the structure, presence of the amine groups, and possible impact of unreacted amines.

We acknowledge that you have recognized at least 16 representative structures. As their variability in concentrations within the Substance is high, it requires further assessment by applying a sound scientific approach. Moreover, in your comments you state that the variability refers to the substance as manufactured in different sites and with a variability of conditions for raw material and manufacturing process. ECHA is not in a position to indicate the representative structures and their concentrations to select for further testing as you, based on your knowledge of your Substance, shall select the representative structure(s) and concentration(s) that will cover the Substance. In addition as indicated in ECHA Guidance R.11, you must report any relevant information justifying your selection.

However once selected the test material should undergo sufficient characterization that would allow establishing the analytical protocol for further testing. Therefore, a thorough characterisation of the test material is a pre-requisite for most information requirements, as Article 13(4) of REACH stipulates "Ecotoxicological and toxicological tests and analyses shall be carried out in compliance with the principles of good laboratory practice".

On this basis, the information requirement is not fulfilled.

#### *Study design*

The Substance is difficult to test. OECD TG 202 specifies that for difficult to test substances, the OECD GD 23 is to be followed. To get reliable results, the substance properties need to be considered when performing the test, in particular with regard to the test design; including exposure system, test solution preparation, and sampling. OECD GD 23 (Table 1) describes testing difficulties related to a specific property of the substance. You may use the approaches

described in OECD GD 23 or other approaches if more appropriate for your substance. The approach selected must be justified and documented.

Due to the substance properties it may be difficult to achieve and maintain the exposure concentrations. Therefore, you have to demonstrate that the concentration of the substance is stable throughout the test (i.e. measured concentrations remains within 80-120% of the nominal concentration). If it is not possible to demonstrate the stability, you must express the effect concentration based on measured values as described in the applicable test guideline. In case a dose-response relationship cannot be established (no observed effects), you must demonstrate that the test solution preparation method applied was sufficient to maximise the concentration of the Substance in the test solution. Furthermore, exposure concentrations must be below the critical micelle concentration (CMC). This will ensure that test organisms are exposed to the freely dissolved chemical species and not the micelle which can alter the uptake of the test chemical.

### 3. Growth inhibition study aquatic plants

Growth inhibition study aquatic plants is an information requirement under Annex VII to REACH (Section 9.1.2).

You have provided the following information:

- [REDACTED] 2013, key study, according to OECD TG 201 with the Substance;

We have assessed this information and identified the following issues:

A. To be adequate for the purpose of classification and labelling and/or risk assessment of the Substance, the study must be conducted in accordance with the applicable OECD test guidelines or other internationally recognised test methods (Article 13(3) of REACH). For the purpose of classification and labelling, as set out in the CLP Regulation, the study must provide information on intrinsic properties i.e. the basic properties of a substance or mixture as determined in standard tests or by other means designed to identify hazards. This is to be derived without consideration of exposure under realistic environmental conditions<sup>5</sup>. As a consequence of the above, studies performed with modification to standard tests procedures impacting exposure cannot be considered relevant to derive intrinsic properties.

To fulfil the information requirement, a study must comply with OECD TG 201 and the requirements of OECD GD 23 (ENV/JM/MONO(2000)6/REV1) if the substance is difficult to test (Article 13(3) of REACH). Therefore, the following requirements must be met:

Validity criteria

- the coefficient of variation of average specific growth rates during the whole test period in replicate control cultures is  $\leq 7\%$  in tests with *Pseudokirchneriella subcapitata*.

In addition:

- one of the two alternative growth media (i.e. the OECD or the AAP medium) is used. Any deviations from recommended test media must be described in details and justified in a way that ensures that the objective of the study is reached;
- use of a reliable analytical method for the quantification of the test material in the test solutions with reported specificity, recovery efficiency, precision, limits of determination (i.e. detection and quantification) and working range, when available. Alternatively, a justification why the analytical monitoring of exposure concentrations is not technically feasible must be provided; For this purpose, a sufficiently sensitive analytical method

<sup>5</sup> CLP Guidance, Section 1.1.3.

must be used for the analysis of the test chemical in the test solutions or a statement from an analytical chemist must be provided to justify why lower detection limits (LOD) were not feasible (any preliminary analytical efforts should also be described in the report);

- the results can be based on nominal (or measured initial concentration) only if evidence is provided that the concentration of the test material has been maintained within 20 % of the nominal (or measured initial concentration) throughout the test.

The Substance is UVCB, highly adsorptive (the estimated log K<sub>oc</sub> ranges from 6.5 to 8.6) and based on structural formula it indicates some surface active properties.

Your registration dossier provides an OECD TG 201 study showing the following:

- Information on one of the validity criteria of the test, meaning information on the coefficient of variation of average specific growth rates during the whole test period in replicate control cultures is not provided.
- The test medium was prepared by using 50% of river water and 50% of the OECD medium. The natural river water had the following characteristics: DOC of 2.98 mg/L and suspended matter of 13.4 mg/L. You provide the following justification for the deviation from standard medium: *OLEIC\_DimerFA\_TETA\_PAA has low water solubility and may sorb to organic and inorganic materials by different mechanisms. Due to these properties the test item was difficult to test in artificial water (e.g. sorption to the test organism and walls of the test vessel). Natural river water contains particulate as well as dissolved organic carbon to which the test item can sorb partially preventing that the test item settles onto surfaces. The sorbed fraction of the test item was difficult to extract from the test system which normally leads to low analytical recoveries. Nevertheless the test item was present in the test system and therefore available for exposure (dissolved in water and sorbed).*
- Analytical monitoring of exposure concentrations was not performed. You provide the following justification: *No determination of the test item concentrations was carried out. Preliminary investigations (non GLP) including the use of different analytical techniques showed that no specific method was available that meets the required sensitivity in the range of the test concentrations.* Moreover you summarised the methods you tried to use: the photometric method (limit of quantification of 1.6 mg/L, 230 nm wavelength), the evaporative light scattering (ELS) detection (limit of detection above 10 mg/L) and the liquid chromatography with electrospray ionisation in positive mode (LC-ESI-MS).
- Effect values were based on nominal concentrations and you have not provided any evidence that the exposure concentrations have been maintained for the test substance during the study period.

The Substance is difficult to test due to the adsorptive and potentially surface active properties as explained above.

Moreover, the study has the following deviations from the requirements of OECD TG 201 and OECD GD 23:

- In the absence of information on coefficient of variation of average specific growth rates in the controls, you have not demonstrated that the validity criteria of OECD TG 201 are met.
- The study was conducted with non-standard test media (natural water) and the provided justification is not acceptable for the reasons explained in detail under request in Appendix A, Section 2, hence the study does not meet the specifications given in OECD TG 201.
- No analytical monitoring was conducted and the given justification is not accepted. (For

detail see explanation under request in Appendix A, Section 2);

- Since the test substance is highly adsorptive, it is expected that considerable losses will occur during the exposure period. In the absence of analytical monitoring of exposure concentrations, you have not demonstrate that the test substance concentration during the test was maintained within the required 20% of nominal concentrations.

Thus, the requirements listed above are not met and therefore the study is not adequate for the purpose of classification and labelling and/or risk assessment.

B. To comply with this information requirement, the test material in a study must be representative for the Substance (Article 10 and Recital 19 of REACH; ECHA Guidance R.4.1). Therefore, the unambiguous characterization of the composition of the test material is required to assess whether the test material is representative for the Substance.

The information on the composition of the test materials, provided in your dossier is limited in general to the numerical identifier and it does not contain information on the identity and quantitative occurrence of its constituents (groups of). More specifically for the test materials you did not report any other information relevant to identify the tested material and concentration levels of the groups of constituents present in the composition of the test material, such as a specific and detailed description of the manufacturing process (including reactants, ratio of starting material, temperature etc).

The test material composition is not sufficiently characterised, since identity and quantitative occurrence of the constituents is not provided. Therefore, this information is not sufficient to demonstrate that the test material is representative for the Substance.

All comments on the request for Growth inhibition study aquatic plants are identical as for request on Short-term toxicity testing on aquatic invertebrates. Therefore they were already addressed under Section A.2 to which ECHA refers to.

On this basis, the information requirement is not fulfilled.

#### *Study design*

OECD TG 201 specifies that for difficult to test substances OECD GD 23 must be followed. As already explained above, the Substance is difficult to test. Therefore, you must fulfil the requirements described in 'Study design' in Appendix A, Section 2.

**Appendix B: Reasons to request information required under Annex VIII of REACH****1. Short-term toxicity testing on fish**

Short-term toxicity testing on fish is an information requirement under Annex VIII to REACH (Section 9.1.3.).

You have provided the following information:

- [REDACTED] 2013, key study, according to OECD TG 203 with the Substance.

We have assessed this information and identified the following issues:

- A. To be adequate for the purpose of classification and labelling and/or risk assessment of the Substance, the study must be conducted in accordance with the applicable OECD test guidelines or other internationally recognised test methods (Article 13(3) of REACH). For the purpose of classification and labelling, as set out in the CLP Regulation, the study must provide information on intrinsic properties i.e. the basic properties of a substance or mixture as determined in standard tests or by other means designed to identify hazards. This is to be derived without consideration of exposure under realistic environmental conditions<sup>6</sup>. As a consequence of the above, studies performed with modification to standard tests procedures impacting exposure cannot be considered relevant to derive intrinsic properties.

To fulfil the information requirement, a study must comply with OECD TG 203 and the requirements of OECD GD 23 (ENV/JM/MONO(2000)6/REV1) if the substance is difficult to test (Article 13(3) of REACH). Therefore, the following requirements must be met:

- the test medium fulfils the following condition(s): particulate matter  $\leq 5$  mg/L and total organic carbon (TOC)  $\leq 2$  mg/L;
- use of a reliable analytical method for the quantification of the test material in the test solutions with reported specificity, recovery efficiency, precision, limits of determination (i.e. detection and quantification) and working range, when available. Alternatively, a justification why the analytical monitoring of exposure concentrations is not technically feasible must be provided; For this purpose, a sufficiently sensitive analytical method must be used for the analysis of the test chemical in the test solutions or a statement from an analytical chemist must be provided to justify why lower detection limits (LOD) were not feasible (any preliminary analytical efforts should also be described in the report);
- the results can be based on nominal (or measured initial concentration) only if evidence is provided that the concentration of the test material has been maintained within 20 % of the nominal (or measured initial concentration) throughout the test.

The Substance is UVCB, highly adsorptive (the estimated log Koc ranges from 6.5 to 8.6) and based on structural formula it indicates some surface active properties.

Your registration dossier provides an OECD TG 203 study showing the following:

- The test medium used was natural river water with the following characteristics: DOC of 2.98 mg/L and suspended matter of 13.4 mg/L. You provide the following justification for the deviation from standard medium: *OLEIC\_DimerFA\_TETA\_PAA has low water solubility and may sorb to organic and inorganic materials by different mechanisms. Due to these properties the test item was difficult to test in artificial water (e.g. sorption to the test organism and walls of the test vessel). Natural river water contains particulate as well as dissolved organic carbon to which the test item can sorb partially preventing that the test*

<sup>6</sup> CLP Guidance, Section 1.1.3.

*item settles onto surfaces. The sorbed fraction of the test item was difficult to extract from the test system which normally leads to low analytical recoveries. Nevertheless the test item was present in the test system and therefore available for exposure (dissolved in water and sorbed).*

- Analytical monitoring of exposure concentrations was not performed. You provide the following justification: *No determination of the test item concentrations was carried out. Preliminary investigations (non GLP) including the use of different analytical techniques showed that no specific method was available that meets the required sensitivity in the range of the test concentrations.* Moreover you summarised the methods you tried to use: the photometric method (limit of quantification of 1.6 mg/L, 230 nm wavelength), the evaporative light scattering (ELS) detection (limit of detection above 10 mg/L) and the liquid chromatography with electrospray ionisation in positive mode (LC-ESI-MS).
- Effect values were based on nominal concentrations and you have not provided any evidence that the exposure concentrations have been maintained for the test substance during the study period.

The Substance is difficult to test due to the adsorptive and potentially surface active properties as explained above.

Moreover, the study has the following deviations from the requirements of OECD TG 203 and OECD GD 23:

- The study was conducted with non-standard test media (natural water) with TOC above 2 mg/L and particulate matter above 5 mg/L, hence it does not meet the specifications given in OECD TG 203. As explained in detail under request in Appendix A, Section 2. for highly adsorptive substances, the use of natural water as the test medium impacts the exposure to the test substance, decreases bioavailability of the substance and in consequence does not inform on the intrinsic properties of the substance.
- No analytical monitoring was conducted and the given justification is not accepted. (For detail see explanation under request in Appendix A, Section 2);
- Since the test substance is highly adsorptive, it is expected that considerable losses will occur during the exposure period. In the absence of analytical monitoring of exposure concentrations, you have not demonstrate that the test substance concentration during the test was maintained within the required 20% of nominal concentrations.

Thus, the requirements listed above are not met and therefore the study is not adequate for the purpose of classification and labelling and/or risk assessment.

B. To comply with this information requirement, the test material in a study must be representative for the Substance (Article 10 and Recital 19 of REACH; ECHA Guidance R.4.1). Therefore, the unambiguous characterization of the composition of the test material is required to assess whether the test material is representative for the Substance.

The information on the composition of the test materials, provided in your dossier is limited in general to the numerical identifier and it does not contain information on the identity and quantitative occurrence of its constituents (groups of). More specifically for the test materials you did not report any other information relevant to identify the tested material and concentration levels of the groups of constituents present in the composition of the test material, such as a specific and detailed description of the manufacturing process (including reactants, ratio of starting material, temperature etc).

The test material composition is not sufficiently characterised, since identity and quantitative occurrence of the constituents is not provided. Therefore, this information is not sufficient to demonstrate that the test material is representative for the Substance.

In your comments to the draft decision you do not agree to perform the requested study. You argue that algae is the most sensitive trophic level and therefore you believe that repeating the vertebrate test is not in the interest of animal welfare.

We have assessed your comment and identified the following issue(s).

As specified in the ECHA Guidance R.7b, for PNEC derivation, "if there is compelling evidence, to suggest that the fish value is likely to be at least a factor of about 10 less sensitive than invertebrates or algae there are no further requirements for acute fish testing".

All of the short-term studies reported in your registration dossiers are considered incompliant with the respective REACH standard information requirements as explained under requests A2, A3 and B1 of this decision. There is therefore no reliable evidence to show that a trophic level would be less sensitive than another. Furthermore, your claim is not even supported by the data referred to by you and submitted in your registration dossier since you have reported for algae the 72-h ErC50 value of 4.34 mg/L, for fish and Daphnia you reported a value of 7.07 mg/L (for the 96-h LC50 and 48-h EC50 respectively). These effect values do not differ by a factor of ten.

Your general comments on selection of the test material has been addressed under Section A.2 to which ECHA refers to.

On this basis, the information requirement is not fulfilled.

#### *Study design*

OECD TG 203 specifies that for difficult to test substances OECD GD 23 must be followed. As already explained above, the Substance is difficult to test. Therefore, you must fulfil the requirements described in 'Study design' in Appendix A, Section 2.

### **2.-5. Simulation testing on ultimate degradation in surface water; soil simulation testing; sediment simulation testing and identification of degradation products (triggered by Annex VIII, Section 9.2., column 2)**

Further degradation testing must be considered if the chemical safety assessment (CSA) according to Annex I indicates the need to investigate further the degradation of the substance (Annex VIII, Section 9.2., column 2).

This information requirement is triggered in case the chemical safety assessment (CSA) indicates the need for further degradation investigation (Annex I, Section 4; Annex XIII, Section 2.1), such as if the substance is a potential PBT/vPvB substance (ECHA Guidance R.11.4). This is the case if the Substance itself or any of its constituent or impurity present in concentration  $\geq 0.1\%$  (w/w) or relevant transformation/degradation product meets the following criteria:

- The Substance is potentially persistent or very persistent (P/vP) as it is not readily biodegradable (*i.e.*  $<60\%$  degradation in OECD TG 301 B/D)
- The Substance is potentially bioaccumulative or very bioaccumulative (B/vB) (e.g.  $\log K_{ow} > 4.5$ ).

Screening information provided in your dossier indicates that the Substance may have PBT/vPvB properties:

- The Substance is potentially P or vP since it is not readily biodegradable (15% degradation in 28 days and 19% in 60 days in the OECD TG 301D test and 0-27% in 28 days and 0-70% in 74 days in the OECD TG 301B test).
- It is not possible to conclude on the B or vB potential because as specified in request in Appendix C, Section 7 below, there is currently no compliant information on Bioaccumulation and further testing is therefore requested.

The information above indicates that the Substance is a potential PBT/vPvB substance. Therefore, the chemical safety assessment (CSA) indicates the need for further degradation investigation.

The examination of the adaptation proposed, as well as the selection of the requested test and the test design are addressed in Appendix C, Sections 3-6. In addition, your comments related to requests for simulation studies and identification of degradation products are addressed in in Appendix C, Sections 3-6.

#### **6. Bioaccumulation in aquatic species (triggered by Annex I, Sections 0.6.1 and 4; Annex XIII, Section 2.1)**

Bioaccumulation in aquatic species is required for the purpose of PBT/vPvB assessment (Annex I, Sections 0.6.1 and 4 to REACH).

Annex I, Section 4 requires that the CSA includes the PBT (persistent, bioaccumulative and toxic) and vPvB (very persistent and very bioaccumulative) assessments.

In accordance with Annex XIII, Section 2.1., if the result of the screening tests or other information indicate that the substance may have PBT or vPvB properties, further testing on bioaccumulation as set out in Section 3.2 is required.

As described above in Appendix B, Sections 2-5, screening information provided in your dossier indicates that the Substance may have PBT/vPvB properties. The available screening information is not sufficient to conclude on the B/vB properties of the Substance, and therefore further testing is required.

The examination of the adaptation proposed, as well as the selection of the requested test and the test design are addressed in Appendix C, Section 7. In addition, your comments related to the request for bioaccumulation study are addressed in in Appendix C, Sections 7.

**Appendix C: Reasons to request information required under Annex IX of REACH**

- 1. Long-term toxicity testing on aquatic invertebrates; and**
- 2. Long-term toxicity testing on fish**

Long-term toxicity testing on aquatic invertebrates is an information requirement under Annex IX to REACH (Section 9.1.5.).

Long-term toxicity testing on fish is an information requirement under Annex IX to REACH (Section 9.1.6.).

You have adapted this information requirement according to Annex IX, Section 9.1, Column 2 with the following justification: *In the chemical safety assessment performed in connection with Annex I no risk was identified. Consequently, in accordance with Column 2 of REACH Annex IX, the study does not need to be conducted as all identified uses of the substance are assessed as safe for the environment.*

We have assessed this information and identified the following issue:

Under Section 9.1., Column 2, Annex IX to REACH, the study may be omitted if the Chemical Safety Assessment demonstrates that risks towards the aquatic compartment arising from the manufacture and use of the substance are controlled (Annex I, Section 0.1). The justification for this adaptation must be documented in the Chemical Safety Report (CSR) and include all the following elements:

- the predicted no effect concentrations (PNEC) for the aquatic compartment which must be based on reliable information on the hazardous properties of the Substance on at least three trophic levels.

For the reasons explained under requests in Appendix A, Sections 2 and 3; and Appendix B, Section 1, your dossier does not include reliable hazard information for the Substance on at least three trophic levels.

Therefore, a reliable PNEC cannot be derived and your adaptation is rejected.

In your comments to the draft decision you do not agree to conduct the requested studies. You claim that the information available from the present acute studies, conducted in river water, suggests low toxicity to aquatic organisms. You also indicate issues with analytical testing methods stating that the substance is difficult to test due to its low water solubility and surface activity. You note that the studies conducted on natural water also suggest that algae would be the most sensitive species.

Moreover in your comments, on one hand you propose *"to investigate water solubility and revisit the acute aquatic toxicity endpoint study records with scientifically justified QSAR modelling before committing to further testing in vertebrate animals"*. On the other hand you bring a list of arguments explaining why long-term studies are not needed: you state that *"the substance is inherently biodegradable and therefore long-term toxicity is not a concern"*, you claim that all RCRs are below 1, you also claim that *"a request for long term testing in fish is unjustified at this time"* and *"ECHA have requested further investigation of water solubility and therefore committal of the registrants to a fish early life stage study at this stage is considered unjustified."*

We have assessed your comments and identified the following issues.

ECHA notes that following the recent Board of Appeal decision taken for the case (A-011-2018), long-term aquatic toxicity testing on fish and aquatic invertebrates are standard information requirements as indicated at Annex IX, column 1 of section 9.1. Moreover, Annex IX, Section 9.1., Column 2 does not allow omitting the need to submit information on long-term toxicity to fish under Column 1. It must be understood as a trigger for providing further information on long-term toxicity to fish if the chemical safety assessment according to Annex I indicates the need (Decision of the Board of Appeal in case A-011-2018). A direct consequence of the Board of Appeal's decision in case A-011-2018 is that the standard information requirement for long term toxicity in fish under Section 9.1. of Annex IX can only be adapted on the basis of the general rules for adaptation set out in Annex XI of REACH. Your dossier does not contain any valid adaptation under Annex XI.

In consequence the long-term aquatic toxicity studies cannot be omitted based on any of the following arguments:

- the results of the ST aquatic toxicity tests,
- the results of inherent biodegradability,
- the results of the water solubility test.

Therefore, the arguments provided with your comments are not relevant reasons to adapt the information requirements.

In addition all of the short-term studies reported in your registration dossiers are considered non-compliant with the respective REACH standard information requirements as explained under requests A2, A3 and B1 of this decision.

Finally the timeline (39 months) given to you to perform the tests allows for sequential testing. As you indicate in your comments, you may start your testing from deriving the water solubility values and then based on that to design an appropriate testing strategy taking into account REACH adaptation possibilities in particular the possibility of conducting only the long-term aquatic toxicity studies if the substance proves to be poorly water soluble.

Furthermore, in the general comments to the draft decision, you describe the use of the Substance and you indicate that it is incorporated into the epoxy resin-based products with no intended release, with very low potential for any exposure to the environment. Moreover, you state that the Substance is used as a curing agent and *"after curing any potentially unreacted component of the Substance is incorporated into the epoxy resin-based products with no intended release, with very low potential for any exposure to the environment"*. In addition, you state that *"epoxy resins are used widely in the construction industry in coatings, adhesives, flooring (e.g. industrial floors and multi-story car parks), concrete restoration, crack repair and as joint material for tiles. In addition, they are widely used in electrical, electronics, aerospace, automotive, sports goods and other high performance applications"*.

ECHA understands that you are referring to an adaptation under Annex XI, Section 3.2(a)/(b)/(c) (Substance-tailored exposure-driven testing) and notes the following issues.

Under Annex XI, Section 3, this information may be omitted based on the exposure scenario(s) developed in the Chemical Safety Report. The justification must be based on a rigorous exposure assessment in accordance with Annex I, Section 5 and must meet any one of the following criteria:

- (a) It can be demonstrated that all the following conditions are met:
  - i. the absence or no significant exposure in all scenarios of the manufacture and all identified uses referred to in Annex VI, Section 3.5., and
  - ii. a PNEC can be derived from available data, which:
    - o must be relevant and appropriate both to the information requirement to be omitted and for risk assessment purposes and therefore must be based on reliable

- information on the hazardous properties of the substance on at least three trophic levels;
- o must take into account the increased uncertainty resulting from the omission of the information requirement, in this case by selecting an appropriate assessment factor (AF) as described in ECHA Guidance R.10.3.
- iii. the ratio between the results of the exposure assessment (PECs) and the PNEC are always well below 1.
- (b) For substances that are not included in articles, it must be demonstrated for all relevant scenarios that strictly controlled conditions as set out in Article 18(4)(a) to (f) apply throughout the life cycle.
- (c) For substances incorporated in articles with no intended releases, the following conditions are met:
  - i. the substance is not released during its life cycle and,
  - ii. the likelihood that workers and the general public are exposed to the substance under normal or reasonable foreseeable conditions is negligible, and
  - iii. the substance is handled according to the conditions as set out in Article 18(4)(a) to (f) during all manufacturing and production stages including the waste management of the substance during these stages.

As it is difficult to understand to which section of Annex XI 3.2 (a), (b) or (c) you are referring to in your comment, we have assessed all three options:

Option (a) cannot be accepted, as for the reasons explained under request A2, A3 and B1, your dossier does not include reliable information on the hazardous properties of the substance on at least three trophic levels. In absence of reliable data you have no reliable PNEC.

For option (b) you have not demonstrated that environmental exposure throughout the life-cycle including waste stage of the Substance is absent or no significant. For example, you report in the CSR the consumer uses (e.g. Use in adhesives and sealants (ERC 8c) and Use in adhesives and sealants (outdoors) (ERC 8f) and widespread uses by professional workers (e.g. Widespread use leading to inclusion into/onto article (outdoor) and Widespread use leading to inclusion into/onto article (indoor)). These uses are, by definition, considered as widespread (ECHA Guidance R.12) and indicate a potential for release (ECHA Guidance R.16).

For option (c), you do not demonstrate that your substance is incorporated in articles with no intended releases and as indicated under point (b) you do not demonstrate that your substance is handled under strictly controlled conditions during its whole lifecycle.

Therefore, the proposed adaptation cannot be accepted. Your general comments on selection of the test material has been addressed under Section A.2 to which ECHA refers to.

On this basis, the information requirement is not fulfilled.

#### *Study design*

To fulfil the information requirement for the Substance, the Fish, Early-life Stage Toxicity Test (test method OECD TG 210) is the most appropriate (ECHA Guidance R.7.8.2.).

OECD TG 211 and OECD TG 210 specify that for difficult to test substances OECD GD 23 must be followed. As already explained above, the Substance is difficult to test. Therefore, you must fulfil the requirements described in 'Study design' in Appendix A, Section 2.

- 3. Simulation testing on ultimate degradation in surface water;**
- 4. Soil simulation testing;**
- 5. Sediment simulation testing; and**
- 6. Identification of degradation products**

Simulation testing on ultimate degradation in surface water is an information requirement under Annex IX to REACH (Section 9.2.1.2.).

Soil simulation testing and sediment simulation testing are standard information requirement at Annex IX of REACH for substances with a high potential for adsorption to soil and to sediment (Sections 9.2.1.3 and 9.2.1.4.).

Identification of degradation products is an information requirement under Annex IX to REACH (Section 9.2.3.).

The Substance has a high adsorption coefficient ( $\log K_{oc} > 5$ ) and therefore has high potential for adsorption to soil and to sediment.

ECHA understands that you have sought to adapt this information requirement based on Annex IX, Sections 9.2.1.2, 9.2.1.3 and 9.2.1.4., Column 2. You justified the adaptation by stating that *as this substance is considered to be inherently biodegradable it is likely to degrade quickly in the environment. As such, further studies on biodegradation in soil are not considered necessary.*

Under Sections 9.2.1.2, 9.2.1.3 and 9.2.1.4., Column 2 of Annex IX to REACH, the study may be omitted if the Substance is readily biodegradable.

Your registration dossier provides the following:

- You consider the Substance as not readily biodegradable based on studies on analogue substance EC 614-452-7 (15% degradation after 28 days and 19% in 60 days in the OECD TG 301D test and 0-27% in 28 days and 0-70% in 74 days in the OECD TG 301B test).
- You claim that the Substance is inherently biodegradable.
- You have provided no information on the identity of transformation/degradation products for the Substance.

Based on the information provided it is not demonstrated that the condition of the adaptation is met, i.e. that Substance is readily biodegradable. Your claim that the Substance is inherently biodegradable is not substantiated by any scientific evidence and, is not a relevant reason to adapt current information requirements.

In your comments to the draft decision, you question the applicability of the ready biodegradability tests for complex UVCB substances. You claim among others that *"OECD 301B and 301D reported in your dossier are not appropriate for assessing the biodegradation of multiple molecules at once and historically were designed for assessment of single pure substances."* You quote also from the ECHA guidance on Application of the CLP that *"the results of biodegradability tests on complex or multi-constituent substances should be carefully evaluated before use for classification purposes is considered"*.

We have assessed your comments however note that as the ready biodegradability study was not requested in this decision, the comments do not directly address the request for simulation studies and identification of degradation products included in this decision. Based on evidence

provided for the ready biodegradation endpoint, we consider the information in the dossier as sufficient to confirm that the substance is not readily biodegradable and hence further testing is required to assess its persistence. Especially that simulation testing and identification of degradation products are standard information requirements under Annex IX to REACH (Sections 9.2.1.2., 9.2.1.3., 9.2.1.4. and 9.2.3.).

Therefore, your adaption is rejected.

In your comments to the draft decision, you do not agree to conduct the requested studies due to the following reasons:

- 1) Instead of conducting the studies you *"propose to invoke an adaptation and use a QSAR approach, similar to the Water solubility approach described and conduct a QSAR assessment on identified components with molecular weights  $\leq 600$ Da."*
- 2) You consider that conducting these studies *"would not produce information of scientific merit or appropriate new information for hazard or risk assessment"* due to A) analytical challenges and B) the variable nature of the UVCB Substance.
- 3) You consider that conducting simulation studies without having reliable information on water solubility (requested under A.1) is unjustified because *"knowledge of the water solubility is a prerequisite for setting up test conditions for a range of fate (e.g. biodegradation, bioaccumulation) and effects studies."*

We have assessed this information and identified the following issues.

- 1) Regarding your proposal to provide QSAR predictions for these endpoints

Under ECHA Guidance R.6.1.7.3. a prediction is adequate for the purpose of classification and labelling and/or risk assessment if the following cumulative conditions is/are met:

- the composition of the substance is clearly defined, and
- representative structure(s) for the assessment are selected.

In addition the following cumulative conditions is/are to be met:

- the composition of the substance is clearly defined, and
- different constituents of the same substance are predicted individually.

As indicated in ECHA Guidance R.11. the use of QSAR predictions for identifying substances for persistence (P and vP) might be used at the screening level. However, QSAR results alone are in most cases not sufficient to conclude on non-persistence but should be supported by additional information. In every case, it should be verified that the QSAR model and predictions are reliable and applicable to the Substance. QSAR predictions can be used as part of a Weight-of-Evidence approach.

From your comments it cannot be concluded that the selection of constituents proposed for the QSAR prediction for persistence would be representative of the whole UVCB, as it is described in the paragraph above.

Moreover, it is not clear which QSAR model(s) you intend to use and if you also intend to provide predictions for identification of degradation products.

Currently, we do not know of any sufficiently reliable models to predict persistence in surface water, soil or sediment. QSAR models for ready biodegradation, such as Biowin, can be used at the screening stage of the PBT assessment and CATALOGIC can also be used for ready biodegradation and mapping of degradation products, given that the predictions are reliable (within the applicability domain of the models) and adequate for the purpose.

In consequence your proposal of using QSAR approach for simulation studies and identification of degradation products is not considered as valid.

2) Regarding your statement that performing the requested studies *"would not produce information of scientific merit or appropriate new information for hazard or risk assessment"*, ECHA notes the following.

2A) Regarding your comments on analytical challenges

You state in your comments that *"the identification of degradation products would be impossible due to a lack of single representative chemical structure and no common structures to facilitate the radiolabelling of all structure within the UVCB"*. You explain why NMR and mass spectrometry would not be suitable methods for the identification of the degradation products of the Substance.

In the comments you also state that *"the variable nature of the components in a UVCB also mean it would be difficult to identify if individual components had undergone degradation, or if they are simply a part of the UVCB itself"* and that *"The results of a simulation study would have no scientific value as the test would only be relevant to the batch of UVCB tested at the point in time when it was tested. Due to the variable nature a second study on a different batch could yield very different results. The information which could be gained about the degradedates from these studies will be limited by the nature of the test material, in particular it's complex constituents, lack of UV chromophore and low molecular weight constituents would require a non-labelled method of analysis which will have the same complications of analytical sensitivity as those identified in previous aquatic testing"*.

Finally, you submit a statement from a contract research laboratory explaining the analytical challenges of complex UVCBs such as the Substance.

We have assessed your comments and identified the following issues.

To fulfil the information requirement, a study must comply with the OECD TGs: 309, 308, 307 (Article 13(3) of REACH). Therefore, the following requirements must be met (among others):

- the analytical method used for the quantification of the test material and its transformation/degradation products needs to be described. The recovery efficiency, precision, limits of determination (i.e. detection and quantification) and working range need to be reported;

The contract research laboratory in their statement indicates that *"given the complexity of the UVCB, radiolabelling the commercial product is not a feasible option and there is no obvious representative candidate molecule for radiolabelling."* Such situation is quite common for UVCB substances and a selected test material shall be identified and prepared prior to the testing. Please note, the laboratory statement is often applicable also for well-defined substances as the tested material shall be appropriately selected, well known, prepared and controlled.

The contract research laboratory also indicates that the selection of the representative candidate molecules for radiolabelling must be carefully performed. You are expected to perform this selection by the use of your knowledge of the Substance and of its molecular structures.

We acknowledge that studies on the rate of degradation conducted with non-radiolabelled test material present more limitations on the information that can be obtained, since with radiolabelled test material it is possible to accurately measure multiple parameters such as mineralisation and the amount of unextractable material (therefore to calculate carefully the mass balance). With the use of radiolabelled test material it is possible also to quantify and identify degradation products.

Despite the relevance of the use of radiolabelling and the more efficient monitoring of degradation product it appears that you have decided to only consider analytical methods applied to not radiolabelled test material and you concluded that *"due to the complex nature of the UVCBs and lack of test design appropriate for measuring the degradation of UVCB/mixtures. In addition, the identification of degradation products would be impossible due to a lack of single representative chemical structure and no common structures to facilitate the radiolabelling of all structure within the UVCB."* Please be aware that on the contrary the identification of degradation products can be performed for more than one structures as those structures, within a sound analytical protocol, are known (i.e. the simplicity of the molecular structures within this UVCB substance the components will be ultimately biodegradable and many of the structural moieties are expected to biodegrade quickly), and the degradation are better identified when derived by radiolabelled material.

Regarding your statement related to the presence of a UV chromophore, we would like to highlight that the presence of a UV chromophore is only relevant if a photometric method is used. This is not the case and therefore the lack a UV chromophore is not an issue. It is also important to stress that the comparison with a reference standard shall be always performed with the same analytical detection method as used for the test sample.

In regards to your comment on NMR method, the applicability of this method shall be assessed on the basis of a full method taking into account all phases of the analytical protocol. Moreover there are various available extraction and concentration methods that result in an increase of the detection limit of the substance. Also the statement on mass spectrometry cannot be accepted as the potency of the mass spectroscopy techniques and the number of their varieties make your statement unjustified.

Finally, the information on the degradation products is necessary to better assess the substance properties. Moreover, the lack of a UV chromophore has no impact on the selection of the monitoring analytical methods and it is not clearly explained and justified why the nature of the test material would require a non-labelled method of analyses.

## 2B) Regarding your comments on the variable nature of the UVCB Substance

To comply with this information requirement, the test material in a study must be representative for the Substance (Article 10 and Recital 19 of REACH; ECHA Guidance R.4.1). Therefore, unambiguous characterization of the composition of the test material chosen is required to assess whether the test material is representative for the Substance.

You declare that "the results of a simulation study would have no scientific value as the test would only be relevant to the batch of UVCB tested at the point in time when it was tested. Due to the variable nature a second study on a different batch could yield very different results". With this statement you confirm that a thorough characterisation of the test material is a pre-requisite for most information requirements. As indicated above, the unambiguous characterization of the composition of the test material is required to assess whether the test material is representative for the Substance.

Your general comments on selection of the test material has been addressed under Section A.2 to which ECHA refers to.

3) In your comments you claim that "ECHA have requested further investigation of water solubility and therefore committal of the registrants to higher tier simulation studies at this stage is considered unjustified".

The timeline (39 months) given to you to perform the tests allows for sequential testing of water solubility and simulation studies (including identification of degradation products) and designing an appropriate testing strategy. As you indicate in your comments, you may start your testing from deriving the water solubility values and then based on that to design an appropriate testing strategy with a possibility of performing simulation studies in a sequence.

On this basis, the information requirements are not fulfilled.

#### *Study selection and design*

Under Annex XIII, the information must be based on data obtained under conditions relevant for the PBT/vPvB assessment. Therefore:

- You must perform the OECD TG 309 test, by following the pelagic test option with natural surface water containing approximately 15 mg dw/L of suspended solids (acceptable concentration between 10 and 20 mg dw/L) (ECHA Guidance R.11).
- You must perform the OECD TG 307 test using five soils representing a range of relevant soils (*i.e.* varying in their organic content, pH, clay content and microbial biomass).
- You must perform the OECD TG 308 test using two sediments. One sediment should have a high organic carbon content (2.5-7.5%) and a fine texture, the other sediment should have a low organic carbon content (0.5-2.5%) and a coarse texture.
- You must perform the tests at the temperature of 12°C, the average environmental temperature for the EU (ECHA Guidance R.16, Table R.16-8). Performing the tests at this temperature is in line with the applicable test conditions of the OECD TG 307.

Non-extractable residues (NER) must be quantified in all simulation studies. The reporting of results must include a scientific justification of the used extraction procedures and solvents. By default, total NER is regarded as non-degraded Substance. However, if reasonably justified and analytically demonstrated a certain part of NER may be differentiated and quantified as irreversibly bound or as degraded to biogenic NER. Such fractions could be regarded as removed when calculating the degradation half-life(s) (ECHA Guidance R.11).

For the information on degradation products you must obtain this information while performing the simulation studies. You must provide a scientifically valid justification for any other method you have used for identification of the transformation/degradation products. Identity, stability, behaviour, and molar quantity of the degradation/ transformation products relative to the Substance must be evaluated and reported, when analytically possible. In addition, degradation half-life, potential for bioaccumulation and toxicity of the transformation/degradation product must be investigated.

## **7. Bioaccumulation in aquatic species**

Bioaccumulation in aquatic species, preferably fish is a standard information requirement at Annex IX of REACH.

You have sought to adapt this information requirement by using data from Qualitative or quantitative structure-activity relationship (QSAR) in accordance with Annex XI, Section 1.3.

We have assessed this information and identified the following issue:

Annex XI, Section 1.3. states that results obtained from valid QSAR models may be used instead of testing when the following cumulative conditions are met, in particular:

- the substance falls within the applicability domain of the QSAR model;
- the results are adequate for classification and labelling and/or risk assessment.

To consider the prediction adequate for REACH purposes, among others, predictions must cover all the relevant structures of the Substance. Specifically for UVCB substances, a set of representative structures for each constituent should be identified and subject to prediction (ECHA Guidance R.6, Section R.6.1.7.3).

Moreover for surface active substances, log Kow is not a valid descriptor to predict bioaccumulation potential of the substance (ECHA Guidance R.7c, Appendix R.7.10-3)

Your Substance is a UVCB and based on structural formula it indicates some surface active properties.

In your registration dossier bioaccumulation was calculated as BCF from BCFBAF v 3.01 model of EpiSuite. The BCF calculation was derived:

- using the structure of:  
CCCC=CCC=CCCCCCCCC(=O)NCCNCCNCCNC(=O)CCCCCCCC=CCCCCCC;
- based on the constituent's predicted Log Kow value (10.34).

1. You have predicted the BCF value for a single structure. As explained above, a single structure, even if fulfilling the requirements under Annex XI, Section 1.3. for a QSAR prediction, is not adequate to cover the bioaccumulation endpoint of a UVCB substance.
2. The BCFBAF calculations are based on log Kow. As the Substance indicates some surface active properties, the provided QSAR prediction based on log Kow is considered not adequate to reliably predict the bioaccumulation of the Substance.

Due to the above, the prediction is considered as not adequate for the purpose of classification and labelling and/or risk assessment.

As a consequence, the adaptation you provided does not fulfil the criteria specified in Annex XI, Section 1.3. and it is therefore rejected.

In your comments to the draft decision you acknowledge that the QSAR prediction for bioaccumulation provided in the dossier is not adequate. However, you do not agree to conduct the requested study due to the following reasons:

- 1) You propose to provide in an updated dossier new QSAR predictions for bioaccumulation using more suitable tool for predictions due to "*advancements in in silico QSPR technology.*" In addition you inform that "*further justification will be provided and the predictions based on multiple constituents of the UVCB that are deemed representative of the substance.*"
- 2) You state that you "*understand the request is based on uncertainty in the current log Kow, biodegradability and water solubility measurements. However, this uncertainty is not suitable*

*to justify the need for the bioaccumulation study and the committal of significant numbers of vertebrate animals (>400)."* Therefore, you propose *"to invoke further adaptations and create a weight of evidence, by refinement of the log Kow and water solubility values before committing to bioaccumulation testing"*

Moreover you consider that conducting this study will *"not produce information of scientific merit or appropriate new information for hazard or risk assessment"* due to A) analytical challenges and B) the variable nature of the UVCB Substance, since you claim that *"The information which could be gained about bioaccumulation from a study will be limited by the nature of the test material and it's complex constituents, lack of UV chromophore and low molecular weight constituents would require a non-labelled method of analysis which will have the same complications of analytical sensitivity as those identified in previous aquatic testing"*.

3) You consider that conducting a bioaccumulation study without having reliable information on water solubility (requested under A.1) is unjustified because *"knowledge of the water solubility is a prerequisite for setting up test conditions for a range of fate (e.g. biodegradation, bioaccumulation) and effects studies."*

We have assessed this information and identified the following issues.

1) Regarding your proposal to provide new QSAR predictions for bioaccumulation

In addition to the cumulative conditions for obtaining valid results from QSAR models mentioned above, the following cumulative conditions are to be also met:

- the composition of the substance is clearly defined, and
- different constituents of the same substance are predicted individually.

From your comments, it seems that you intend to apply the same BCFBAF model for the updated predictions, although this is not fully clear. Please note that the use of BCFBAF calculations and the use QSAR predictions based on logKow are already assessed and addressed above.

Moreover the BCF predictions (and the WSKOW predictions) both in BCFBAF (Episuite) model and Catalogic BCF models are based on logKow. As long as there are reliability issues with the logKOW predictions, there will be issues with the BCF predictions, in both models. Moreover there is a risk that even though you would identify a representative number of constituents, some of them (e.g. ██████████) would be outside of the applicability domain of at least the logKOW model (but probably also related models).

2) Regarding your comment on the complexity of the test material and the selection of analytical monitoring method, as already explained under sections (C3-C6) the lack of a UV chromophore cannot impact the selection of the monitoring analytical methods as you have decided to exclude photometric methods. It is also unclear and not justified why the nature of the test material would require a non-labelled method of analyses as such affirmation only derive from a wrong interpretation of the statement of the laboratory.

3) Finally, the timeline (39 months) given to you to perform the tests allows for sequential testing. As you indicate in your comments, you may start your testing from deriving the water solubility values and then based on that to design an appropriate testing strategy taking into account the study design on the OECD TG 305. Moreover please note that the bioaccumulation of each relevant constituent and degradation products shall be assessed to reach a conclusion of PBT properties (ECHA Guidance R.11). Therefore conducting first the studies requested under C3-C6 and identifying the relevant constituents and/or degradation products would be necessary to decide on appropriate test material for the bioaccumulation study.

*Study design*

Bioaccumulation in fish: aqueous and dietary exposure (Method EU C.13 / OECD TG 305) is the preferred test to investigate bioaccumulation (ECHA Guidance R.7.10.3.1.). Exposure via the aqueous route (OECD TG 305-I) must be conducted unless it can be demonstrated that:

- a stable and fully dissolved concentration of the test substance in water cannot be maintained within  $\pm 20\%$  of the mean measured value, and/or
- the highest achievable concentration is less than an order of magnitude above the limit of quantification (LoQ) of a sensitive analytical method.

This test set-up is preferred as it allows for a direct comparison with the B and vB criteria of Annex XIII of REACH.

You may only conduct the study using the dietary exposure route (OECD 305-III) if you justify and document that testing through aquatic exposure is not technically possible as indicated above. You must then estimate the corresponding BCF value from the dietary test data according to Annex 8 of the OECD 305 TG and OECD Guidance Document on Aspects of OECD TG 305 on Fish Bioaccumulation (ENV/JM/MONO(2017)16).

## **Appendix D: Requirements to fulfil when conducting and reporting new tests for REACH purposes**

### **A. Test methods, GLP requirements and reporting**

1. Under Article 13(3) of REACH, all new data generated as a result of this decision must be conducted according to the test methods laid down in a European Commission Regulation or to international test methods recognised by the Commission or ECHA as being appropriate.
2. Under Article 13(4) of REACH, ecotoxicological and toxicological tests and analyses must be carried out according to the GLP principles (Directive 2004/10/EC) or other international standards recognised by the Commission or ECHA.
3. Under Article 10(a)(vi) and (vii) of REACH, all new data generated as a result of this decision must be reported as study summaries, or as robust study summaries, if required under Annex I of REACH. See ECHA Practical Guide on How to report robust study summaries<sup>7</sup>.

### **B. Test material**

Before generating new data, you must agree within the joint submission on the chemical composition of the material to be tested (Test Material) which must be relevant for all the registrants of the Substance.

#### *1. Selection of the Test material(s)*

The Test Material used to generate the new data must be selected taking into account the following:

- a) the variation in compositions reported by all members of the joint submission
- b) the boundary composition(s) of the Substance,
- c) the impact of each constituent/ impurity on the test results for the endpoint to be assessed. For example, if a constituent/ impurity of the Substance is known to have an impact on (eco)toxicity, the selected Test Material must contain that constituent/ impurity.

#### *2. Information on the Test Material needed in the updated dossier*

- a) You must report the composition of the Test Material selected for each study, under the "Test material information" section, for each respective endpoint study record in IUCLID.
- b) The reported composition must include the careful identification and description of the characteristics of the Tests Materials in accordance with OECD GLP (ENV/MC/CHEM(98)16) and EU Test Methods Regulation (EU) 440/2008 (Note, Annex), namely all the constituents must be identified as far as possible as well as their concentration. Also any constituents that have harmonised classification and labelling according to the CLP Regulation must be identified and quantified using the appropriate analytical methods,

With that detailed information, ECHA can confirm whether the Test Material is relevant for the Substance and whether it is suitable for use by all members of the joint submission.

Technical instructions on how to report the above is available in the manual on How to prepare registration and PPORD dossiers<sup>8</sup>.

<sup>7</sup> <https://echa.europa.eu/practical-guides>

<sup>8</sup> <https://echa.europa.eu/manuals>

## **Appendix E: General recommendations when conducting and reporting new tests for REACH purposes**

### **A. Strategy for the PBT/vPvB assessment**

You are advised to consult ECHA Guidance R.7b (Section R.7.9.), R.7c (Section R.7.10) and R.11 on PBT assessment to determine the sequence of the tests needed to reach the conclusion on PBT/vPvB. The guidance provides advice on 1) integrated testing strategies (ITS) for the P, B and T assessments and 2) the interpretation of results in concluding whether the Substance fulfils the PBT/vPvB criteria of Annex XIII.

In particular, you are advised to first conclude whether the Substance fulfils the Annex XIII criteria for P and vP, and then continue with the assessment for bioaccumulation. When determining the sequence of simulation degradation testing you are advised to consider the intrinsic properties of the Substance, its identified uses and release patterns as these could significantly influence the environmental fate of the Substance. You must revise your PBT assessment when the new information is available.

### **B. Testing strategy for aquatic toxicity testing**

You are advised to consult ECHA Guidance R.7b, (Section R.7.8.5) which describes the Integrated Testing Strategy, to determine the sequence of aquatic toxicity tests and testing needed.

### **C. Environmental testing for substances containing multiple constituents**

Your Substance contains multiple constituents and, as indicated in ECHA Guidance R.11 (Section R.11.4.2.2), you are advised to consider the following approaches for persistency, bioaccumulation and aquatic toxicity testing:

- the "known constituents approach" (by assessing specific constituents), or
- the "fraction/block approach, (performed on the basis of fractions/blocks of constituents), or
- the "whole substance approach", or
- various combinations of the approaches described above

Selection of the appropriate approach must take into account the possibility to characterise the Substance (i.e. knowledge of its constituents and/or fractions and any differences in their properties) and the possibility to isolate or synthesize its relevant constituents and/or fractions.

## **Appendix F: Procedure**

This decision does not prevent ECHA from initiating further compliance checks at a later stage on the registrations present.

ECHA followed the procedure detailed in Articles 50 and 51 of REACH.

The compliance check was initiated on 13/08/2019.

ECHA notified you of the draft decision and invited you to provide comments within the notification.

ECHA took into account your comments and did not amend the requests.

ECHA notified the draft decision to the competent authorities of the Member States for proposals for amendment.

As no amendments were proposed, ECHA adopted the decision under Article 51(3) of REACH.
