

# Committee for Risk Assessment RAC

#### Annex 1

### **Background document**

to the Opinion proposing harmonised classification and labelling at Community level of Tertbutyl hydroperoxide

EC number: 200-915-7 CAS number: 75-91-2

CLH-O-000001412-86-27/F

The background document is a compilation of information considered relevant by the dossier submitter or by RAC for the proposed classification. It includes the proposal of the dossier submitter and the conclusion of RAC. It is based on the official CLH report submitted to public consultation. RAC has not changed the text of this CLH report but inserted text which is specifically marked as 'RAC evaluation'. Only the RAC text reflects the view of RAC.

Adopted
04 December 2014

# Part A.

#### 1 PROPOSAL FOR HARMONISED CLASSIFICATION AND LABELLING

#### 1.1 Substance

**Table 1:** Substance identity

| Substance name:        | tert-butyl hydroperoxide        |
|------------------------|---------------------------------|
| EC number:             | 200-915-7                       |
| CAS number:            | 75-91-2                         |
| Annex VI Index number: |                                 |
| Degree of purity:      | 68.4-69.6% % (w/w)              |
| Impurities:            | Not relevant for classification |

#### 1.2 Harmonised classification and labelling proposal

Table 2: The current Annex VI entry and the proposed harmonised classification

|  | CLP Regulation |
|--|----------------|
| Current entry in Annex VI, CLP<br>Regulation   | -              |
| Current proposal for consideration by RAC  | Muta 2, H341   |
| Resulting harmonised classification<br>(future entry in Annex VI, CLP<br>Regulation) | Muta 2, H341   |

No classification is proposed according to 67/548/EC as this is no longer required.

# 1.3 Proposed harmonised classification and labelling based on CLP Regulation and/or DSD criteria

 Table 3:
 Proposed classification according to the CLP Regulation

| CLP            | Hazard class   | Proposed       | Proposed SCLs    | Current           | Reason for no                |
|----------------|--|----------------|------------------|-------------------|------------------------------|
| Annex I<br>ref |  | classification | and/or M-factors | classification 1) | classification <sup>2)</sup> |
| 2.1.           | Explosives   |                |                  |                   |                              |
| 2.2.           | Flammable gases  |                |                  |                   |                              |

|                | Acute toxicity - inhalation  |                |                  |                   |                              |
| 3.2.           | Skin corrosion / irritation  |                |                  |                   |                              |
| 3.3.           | Serious eye damage / eye irritation                                      |                |                  |                   |                              |
| 3.4.           | Respiratory sensitisation  |                |                  |                   |                              |
| 3.4.           | Skin sensitisation   |                |                  |                   |                              |
| 3.5.           | Germ cell mutagenicity   | Muta 2, H341   | -                | none              |                              |
| 3.6.           | Carcinogenicity  |                |                  |                   |                              |
| 3.7.           | Reproductive toxicity  |                |                  |                   |                              |
| 3.8.           | Specific target organ toxicity –single exposure                          |                |                  |                   |                              |
| 3.9.           | Specific target organ toxicity  – repeated exposure                      |                |                  |                   |                              |
| 3.10.          | Aspiration hazard  |                |                  |                   |                              |

#### CLH REPORT FOR TERTBUTYL HYDROPEROXIDE

| 4.1. | Hazardous to the aquatic environment |  |  |
|------|--------------------------------------|--|--|
| 5.1. | Hazardous to the ozone layer         |  |  |

**Labelling:** Signal word: Warning

Hazard statements: H341: suspected of causing genetic defects

Not part of an Annex VI entry. Precautionary statements:

#### Proposed notes assigned to an entry:

#### Proposed classification according to DSD Table 4:

Not required.

<sup>1)</sup> Including specific concentration limits (SCLs) and M-factors
2) Data lacking, inconclusive, or conclusive but not sufficient for classification

#### 2 BACKGROUND TO THE CLH PROPOSAL

#### 2.1 History of the previous classification and labelling

The Netherlands was rapporteur for TBHP under the Existing Substances Regulation A RAR was produced and a proposal for harmonized classification and labelling. Recommendations by the Technical Committee on Classification and Labelling (**TC-C&L**) in October 2006 and September 2007 for physical/chemical and human health endpoints (see annexes) and in April 2006 for environmental effects were:

#### **Classification:**

O: R7

R10

Muta Cat 3: R68

C; R34

T: R23

Xn; R21/22

R43

N; R51/53

#### Labelling:

Symbol: O, T, N

R-phrase: 7, 10, 21/22, 23, 34, 43, 68, 51/53

S-phrase: 3/7, 14, 26, 36/37/39, 43, 45, 61

Specific concentration limits were concluded with R37 between 5% < C  $\le$  10% and R43 above C  $\ge$  0.1%.

This classification and labelling would be included in Annex I of EU 67/548 as tert-butyl

hydroperoxide 70% in water because TBHP with less than 30% water is probably explosive.

TBHP has been evaluated by the TC-C&L resulting in a recommendation for classification with Muta Cat.3; R68. The TC-C&L recommendation has not been included in an ATP due to the partial replacement of DSD by CLP. Therefore, a new proposal according to CLP is required. This proposal is limited to the mutagenic properties of TBHP. A re-evaluation by RAC is explicitly requested because of the differences between the DSD and CLP criteria with respect to mutagenicity and because new information regarding mutagenic properties is available. In our opinion TBHP is a local mutagen. However, the CLP states that this hazard class is primarily concerned with substances that may cause mutations in the germ cells of humans that can be transmitted to the progeny. However, the criteria for category 3 are based on effects observed in somatic cells. In this case there seems to be a difference between the concern and the criteria. Therefore, re-evaluation by the RAC is requested.

#### 2.2 Short summary of the scientific justification for the CLH proposal

TBHP is positive in several *in vitro* studies. The *in vivo* dataset is limited and in most studies negative. However, TBHP is positive in a dominant lethal assay in mice after intraperitoneal exposure. This could be a local effect of TBHP because substances can migrate from the abdominal cavity through the inguinal channel to the testis. However, TBHP has been shown to be unstable in blood in *in vivo* ADME studies. Therefore, it is unlikely that TBHP will reach the testis after exposure via normal routes. Therefore, TBHP is considered a local mutagen fulfilling the requirements for Muta 2 (CLP).

#### 2.3 Current harmonised classification and labelling

# 2.3.1 Current classification and labelling in Annex VI, Table 3.1 in the CLP Regulation

None

# 2.3.2 Current classification and labelling in Annex VI, Table 3.2 in the CLP Regulation

None

#### 2.4 Current self-classification and labelling

#### 2.4.1 Current self-classification and labelling based on the CLP Regulation criteria

The self-classification of the registrant is provided in the table below. This classification was only used by 2 out of more than 600 notifiers.

Table 5. Self-classification by the registrant.

| Flam. Liq. 3  | H226 | H226 |                |                                 |
|---------------|------|------|----------------|---------------------------------|
| Org. Perox. F | H242 | H242 |                |                                 |
| Acute Tox. 4  | H302 | H302 | GHS02          |                                 |
| Acute Tox. 3  | H311 | H311 | GHS06          | Eye Dam. 1: C ≥ 1%              |
| Skin Corr. 1C | H314 | H314 | GHS09<br>GHS05 | STOT SE 3: $5\% \le C \le 10\%$ |
| Skin Sens. 1  | H317 | H317 | GHS08          | Skin Sens. 1: C ≥ 0,1%          |
| Eye Dam. 1    | H318 |      | Dgr            |                                 |
| Acute Tox. 2  | H330 | H330 |                |                                 |
| Muta. 2       | H341 | H341 |                |                                 |

#### CLH REPORT FOR TERTBUTYL HYDROPEROXIDE

|--|

An copy of the self-classification as available in the C&L inventory on 8 November 2012 is provided in Annex C. A summary is provided in the table below.

Table 6. Summary of CLP self-classifications

| Type of hazard    | Hazard class        | Number of notifiers  classifying in the hazard  class (percentage of total  notifications) |
|-------------------|---------------------|--|
| No classification |                     | 181 (27%)  |

#### 2.4.2 Current self-classification and labelling based on DSD criteria

**R7 O: Oxidising** 

R10: flammable

Health hazards

Xn; R21/22; harmful in contact with skin and if swallowed

T; R23: toxic by inhalation

C; R34: Corrosive causes burns

Xi; R41; Risk of serious damage to eyes

R43; May cause sensitisation by skin contact

Muta cat 3, R68; Possible risk for irreversible effects

Environmental hazards

N; R51/53

Based on the available registrations (8 November 2012).

#### 3 JUSTIFICATION THAT ACTION IS NEEDED AT COMMUNITY LEVEL

Classification with Muta 2; H341 is normally subject to harmonised classification (CLP article 36.1.b). Other hazard classes were not included, as there is currently no need for harmonisation of these hazard classes.

# Part B.

### SCIENTIFIC EVALUATION OF THE DATA

#### 1 IDENTITY OF THE SUBSTANCE

#### 1.1 Name and other identifiers of the substance

**Table 7:** Substance identity

| EC number:                 | 200-915-7                        |
|----------------------------|----------------------------------|
| EC name:                   | tert-butyl hydroperoxide         |
| CAS number (EC inventory): |                                  |
| CAS number:                | 75-91-2                          |
| CAS name:                  | tert-butyl hydroperoxide         |
| IUPAC name:                | hydroperoxide, 1,1-dimethylethyl |
| CLP Annex VI Index number: |                                  |
| Molecular formula:         | $C_4H_{10}O_2$                   |
| Molecular weight range:    | 90.1                             |

#### **Structural formula:**

| Other organics         | • ≤ 0.4%              |                     |         |

Current Annex VI entry: not relevant

#### Remark:

There are two registrations. The composition of the currently registered substances is deviating from the one mentioned in the RAR. TBHP purity is close to 100% w/w (exact purity is confidential) when the purity is calculated excluding water. The typical water concentration in the solution is 30% (w/w). Information on the impurities in the registered substances is confidential and will be included in IUCLID. The presence of water as a stabilizer is important because TBHP without stabilizer is explosive (see Table 11).

**Table 10:** Additives (non-confidential information)

| Additive | Function | Typical concentration | Concentration range | Remarks |
|----------|----------|-----------------------|---------------------|---------|
| Water    |          | ≤ 30%                 |                     | RAR     |

Current Annex VI entry: -

#### 1.2.1 Composition of test material

The purity of the test material is indicated in the individual test descriptions and is considered relevant for TBHP.

#### 1.3 Physico-chemical properties

The physico-chemical properties for 70% THBP and, where indicated, for 100%

TBHP (= TBHP pure) are presented in Table 9. This table is copied from the RAR.

Table 11: Summary of physico - chemical properties of TBHP<sup>1</sup>

| Property                                     | Value   | Reference   | Comment (e.g. measured or estimated)   |

<sup>1 70%</sup> TBHP and, where indicated, of 100% TBHP

#### 2 MANUFACTURE AND USES

#### 2.1 Manufacture

#### 2.2 Identified uses

Tert-butyl hydroperoxide (TBHP) is primarily used in the chemical industry. TBHP is used as starting material (or intermediate) and as a reactive ingredient (catalyst, initiator or curing agent) (RAR).

According to the registrations there is also professional use including roller application or brushing (PROC 10) and non industrial spraying (PROC 11).

#### 3 CLASSIFICATION FOR PHYSICO-CHEMICAL PROPERTIES

Not relevant as this proposal is limited to classification for mutagenicity.

#### 4 HUMAN HEALTH HAZARD ASSESSMENT

This CLH proposal is based on the risk assessment report (RAR) and the additional information in the Annex XV transitional report of TBHP which is available at:

 $\underline{http://echa.europa.eu/web/guest/information-on-chemicals/transitional-measures/annex-xv-transitional-reports}$ 

Also the REACH registration as available at the ECHA website was used (last visit at 3 April 2012).

#### **RAC** general comment

Tert-butyl hydroperoxide (TBHP) has currently no entry in Annex VI to the CLP Regulation. The dossier submitter proposed only the hazard class mutagenicity for harmonisation

#### 4.1 Toxicokinetics (absorption, metabolism, distribution and elimination)

The text below is a direct copy from the paragraph on Toxicokinetics from the RAR of TBHP. Also the references can be found in the RAR.

#### 4.1.1 Non-human information

#### **Toxicokinetics**

In general, hydroperoxides are known to be reductively metabolized (Casarett and Doull, 1996). The main detoxification pathway is a two-electron reduction by glutathione peroxidase using glutathione to the corresponding alcohol (for TBHP this is 2-methylpropan-2-ol (= tert-butanol)). But when these reducing equivalents have been depleted (i.e. at high concentrations of TBHP), TBHP undergoes a one-electron oxidation generating the peroxyl radical (t-BuO·) or a one-electron reduction generating the tert-butoxyl radical (t-BuO·), the latter being the major process (Davies, 1988). Subsequent fragmentation of the tert-butoxyl radical results in the formation of carbon-centred radicals (CH<sub>3</sub>; Greenley and Davies, 1992). The generation of such radicals has been demonstrated in several in vitro systems, such as human endothelial cells (O'Donnell and Burkitt, 1994), intact skin samples of the mouse (Timmins and Davis, 1993), rat liver microsomes (Greenley and Davies, 1992), and isolated rat liver nuclei (Greenley and Davies, 1994).

It is known from intracerebroventricular research that TBHP easily diffuses across biological membranes (Chang *et al.*, 1995; Di Meo *et al.*, 1997).

#### Studies in animals

#### *In vivo studies*

Inhalation

No information after inhalation exposure was provided because this route of exposure was considered unacceptable on safety grounds (explosion risk after evaporation). The subcutaneous route was tested as a potential surrogate.

#### Dermal

In a preliminary study (de Bie, 2003), two male Wistar rats were dermally exposed on 10 cm<sup>2</sup> shaved skin to 0.5 mg uniformly labelled [<sup>14</sup>C]-TBHP at a concentration of 5% in water for 8 hours using semi-occlusive conditions. Samples of expired air, blood, urine and faeces were taken at several time points for the determination of total radioactivity. Urine samples were also used for metabolic profiling using HPLC. Further, a skin wash sample was taken after 8 hours and a cage wash sample at the end of the collection period. At the necropsy at 8 and 48 hours after the start of treatment, tissues and organs were examined for residual radioactivity.

The total recovery of radioactivity was only 30 and 40%. According to the author, this was probably caused by evaporation during the application of the substance to the skin because the odour of TBHP was noticeable during application. Only 1 to 3% radioactivity was recovered in urine, 0 to 2% in faeces and 22 to 34% in the cage air. This could be due to exhalation and/or evaporation. In the animal sacrificed after 48 hours, 33% radioactivity was found in the air after 8 hours and only 1% between 8 and 48 hours. The amount of radioactivity remaining in the body was 3.5% after 8 hours and 2% after 48 hours. The amount of radioactivity in cage wash and skin wash was approximately 1%. If it is assumed that all radioactivity in the air was due to evaporation, then the total absorption was only 5 to 7% of the total applied amount. This absorption value cannot be used in the risk characterisation because of the (uncontrolled) evaporation. As a result of evaporation, exposure of TBHP via inhalation cannot be excluded. Exposure via inhalation would result in an overestimation of the actual dermal absorption figure. The Cmax, found at 8 hours, was approximately 1 µg/g blood for radioactive equivalents. Radioactivity levels in other organs were highest in the kidneys and liver and approximately 3 times lower in other tissues like testes and lungs. No TBHP but 3 unknown metabolites (U1, U2 and U3) and probably 2-methylpropan-2-ol were found in urine using HPLC. No U2 was found in urine from 0-8 hours but this shifted to only U2 in urine from 24 to 48 hours.

The abstract of a dermal study including the determination of free radicals was provided by the NTP. TBHP was dermally administered in 50 percent aqueous acetone to male Fischer 344 rats at a dosage of 0 or 175 mg/kg bw (Ritchie *et al.*, 2005c). The study animals were administered TBHP 12 times on weekdays only during the 17-day study period. There were eight rats per group and they received 0.5 ml/kg bw. On the last study day, each rat was dosed with one of two spin trap agents (PBN (N-*tert*-butyl-α-phenylnitrone): i.p.; 250 mg/mL; 0.1 mL/100 g body weight, or POBN (α-(4-pyridyl 1-oxide)-N-*tert*-butylnitrone): i.p.; 0.5 g/mL;

0.2 mL/100 g body weight) to allow post-termination assessment of free radical presence in the blood, urine, and in selected organs. The results of the free radical determination were not provided in the abstract but some results were available in a review of the study. There were no increases in free radical formation measured in the lipid extracts of liver, kidney, blood, lung and heart from the animals.

#### Comparison of oral and subcutaneous exposure

In a preliminary study (de Bie, 2003), single male fasted Wistar rats were exposed by gavage (PO) or by subcutaneous injection (SC) to 10 (low) or 100 (high) mg/kg bw uniformly labelled [14C]-TBHP. All doses were diluted in saline and provided at 20 ml per kg bw. Samples were collected for total radioactivity determination from expired air, blood, faeces and urine at several time points up to necropsy at 48 hours. At necropsy, residual radioactivity was determined in several organs. Further, a cage wash was performed to determine residual radioactivity. Urine samples were also analysed by HPLC to profile the metabolites with and without enzymatic digestion. Metabolites were identified using LC-MS/MS.

Only the animal exposed to 100 mg/kg bw via subcutaneous exposure showed drowsiness and slow respiration between 10 and 60 minutes after dosing. After 48 hours, 55 to 69% of the applied radioactivity was excreted in the urine, 1 to 2% in the faeces and 9 to 15% exhaled. The cage wash accounted for 1 to 3% and the radioactivity retained in the body for 10 to 31%. This resulted in a recovery of 94 to 97% of radiolabel. The main difference between the treatments was the increase in retained radioactivity in SC treated animals compared to the oral treated animals. The results indicate (n=1) that TBHP is almost completely absorbed after oral exposure. The blood kinetics are shown in **Table 4.1**. The results indicate that SC exposure resulted in somewhat longer terminal half-lives and higher AUC values for total radioactivity.

Table 4.1 <sup>14</sup>C Blood kinetics in male rats (preliminary study)

| Parameter          |            | PO low | SC low | PO high | SC high |
|--------------------|------------|--------|--------|---------|---------|
| Cmax               | μg/ml      | 9.2    | 11.1   | 68.5    | 91.7    |
| C at 48 hours      | $\mu g/ml$ | 2.6    | 4.7    | 13.3    | 50.3    |
| Tmax               | h          | 8      | 8      | 8       | 24      |
| Terminal half-life | h          | 21.8   | 32.1   | 17.1    | 27.7    |
| AUC 0-48 h         | μg/ml.h    | 270    | 278    | 1573    | 3056    |
| AUC 0-infinity     | μg/ml.h    | 351    | 597    | 1901    | 5060    |

The highest tissue radioactivity concentrations at 48 hours after oral and subcutaneous administration were found in the kidney followed by liver and blood. Somewhat lower concentrations were found in lungs, testes and carcass but the difference between the highest and the lowest value for each treatment was a factor 3 at most, indicating an almost equal distribution over the body. No TBHP but 4 unknown metabolites and probably 2-methylpropan-2-ol were detected in the urine. During the first 8 hours mainly U1 was excreted in the low dose animals and U3 in the high dose animals. This shifted at later

sampling times to almost only U2. Treatment with beta-glucuronidase/aryl-sulphatase did not change the metabolic profiles. The metabolites could not be identified.

The provided preliminary ADME study indicated only minor differences between oral and SC exposure.

#### Oral

Male Wistar rats (n unknown) were treated with a spin trapping agent (PBN (phenyl-N-tertbutylnitrone) or POBN (α-(4-pyridyl-1-oxide)-N-tert-butylnitrone)) and with TBHP through gavage at dose levels of 0.5 or 1.0 ml/kg bw for 70% TBHP (solvent unknown) or 0.4 ml/kg bw for 90% [13C]-TBHP (solvent unknown) (Hix et al., 2000). Bile was collected via bile duct cannulation at 20, 40 and 60 minutes after TBHP exposure. At 60 minutes, the animals were sacrificed and samples from blood, liver and stomach collected. The radicals that reacted with the spin trap were determined using electron paramagnetic resonance. Products of the reaction of the radicals with the spin trap (adduct) were found in the three tissues studied but no quantitative information was provided. The adduct in the blood was mainly confined to the erythrocytes and was identified as the PBN-thiylhemoglobin radical adduct. The EPR spectra of the kidney and liver were characteristic of PBN-alkyl radical adducts. The EPR signal in the bile increased from the first sample (0-20 minutes) to the second sample (20-40 minutes) but then decreased. According to the authors, this was probably due to extensive haemoglobin oxidation and impaired urine excretion by all treated rats. One adduct in the bile was characterised using [13C]-TBHP as PBN-CH3 radical adduct or POBN-CH3 radical adduct. The identity of the main adduct in the bile remained unknown. Also methyl DNA adducts were found in liver and stomach (see B.5.7.2). It should be noted that the tested dose levels were above or comparable to the LD50.

The abstract of an oral study including the determination of free radicals was provided by the NTP. TBHP in 0.5 percent aqueous methylcellulose was delivered by gavage to male Fischer 344 rats at dosages of 0 or 175 mg/kg bw at a volume of 5 mL/kg bw (Ritchie *et al.*, 2005a). Animals were dosed daily 12 times (weekdays only) during the 17-day study period. There were eight rats in each treatment group. On the last study day, each rat was treated with one of two spin-trap agents (PBN: i.p.; 250 mg/mL; 0.1 mL/100 g body weight, or POBN: i.p.; 0.5 g/mL; 0.2 mL/100 g body weight) to allow post-termination assessment of free radical presence in the blood, urine, and in selected organs (liver, right kidney, heart, and lung). However, the results of this study were not provided in the abstract but some results were available in a review of the study. A two to five fold increase in free radical formation in the lipid extracts of the tissues was found which was statistically significant in liver, kidney and blood. Liver had the highest (about five fold) increase in free radical formation.

#### Subcutaneous versus intravenous

Based on the comparable absorption, distribution, metabolism and excretion after oral and subcutaneous exposure in the preliminary study (de Bie, 2003), the main study (de Bie and Grossouw, 2004) was performed using the subcutaneous route. These results were expected also to be relevant to the dermal and inhalatory route.

Groups of 4 to 5 male and sometimes female Wistar rats were subcutaneously exposed to a single dose of 5 or 50 mg/kg bw/day [<sup>14</sup>C]-TBHP in saline. The TBHP contained

approximately 5% 2-methylpropan-2-ol. As a reference, a group of male rats was treated intravenously with 5 mg/kg bw [<sup>14</sup>C]-TBHP. Also one group was treated subcutaneously with 5 mg/kg bw after an oral 14 day pre-treatment with 50 mg/kg bw/day unlabelled TBHP. In all groups, samples from blood, expired air, urine and faeces were collected at several time points for total radioactivity determination and metabolic profiling with or without acid or alkali hydrolyses. At necropsy on day 7 after treatment, samples of several tissues and organs were collected for the same determinations. Also, the GSH and GSSG concentration was determined in selected tissues. Further, a cage wash sample was collected at the end of the collection period.

#### **Blood kinetics**

The kinetic parameters for total radioactivity in male rats after a single SC and IV exposure were almost comparable (**Table 4.2**), indicating almost complete absorption after SC exposure. Cmax, Tmax and AUC for total radioactivity were somewhat lower in females compared to males which is probably caused by the higher VD and lower T1/2 in females. No effect of pre-treatment was seen on the kinetic parameters. Also, no dose dependent differences were seen. Seen the quick metabolism of TBHP to 2-methylpropan-2-ol, the AUC and T1/2 of TBHP itself is probably much lower than for total radioactivity.

| <b>Table 4.2</b> | <sup>14</sup> C-Blood | kinetics in | rats | (main study) |  |
|------------------|-----------------------|-------------|------|--------------|--|
|------------------|-----------------------|-------------|------|--------------|--|

#### Absorption and excretion

In all groups between 79 and 81% of the injected radioactivity was excreted in the urine mainly within the first 48 hours. Only in females receiving a single dose of 50 mg/kg bw, 68% was excreted in urine. Faeces accounted for 1 to 2% of the injected radioactivity, cage wash for approximately 0.5% and approximately 1% was retained in the body after 7 days. Tissue residues in females were somewhat lower compared to man. Further, approximately 2% was exhaled as carbon dioxide and 5 to 9% was exhaled as volatiles. Only in the females receiving a single dose of 50 mg/kg bw, 15% volatiles were exhaled. Total recovery was between 88 and 93% of the injected amount of radioactivity. The results indicate no difference between IV and SC treatment, no effect of pre-treatment, proportionality to dose and only some minor differences between males and females.

#### Tissue distribution and elimination

The highest residue levels (total radioactivity) were found in the kidney. Residue levels in most other organs were approximately 50% of the kidney levels but clearly lower in fat. A two-phase residue elimination of radioactivity was seen. In the first phase between 2 and 36 hours, an elimination with a half-life of approximately 12 hours was seen. The half-life in the second phase between 36 and 96 hours was slower with a half-life of approximately 50 hours. The half-lives were somewhat higher in high dose males compared to low dose males resulting in proportionally somewhat higher residue levels at the high dose after 7 days. Somewhat higher residue levels (total radioactivity) were also found in the pre-treated group. Further, residue levels were lower in the females compared to the males. The final residue levels after IV treatment were somewhat lower compared to SC treatment.

#### Metabolite profiling

No TBHP was found in the urine collected over 96 hours but 3 major metabolites (U1, U2 and U3) and 6 minor metabolites could be detected. The minor metabolite 2-methylpropan-2-ol was mainly found at the earlier collection times. Also, all three major metabolites were found at the earlier time points shifting to only U2 at later time points after the low dose and mainly U2 after pre-treatment and the high dose. Comparable metabolic profiles over 96 hours were seen between IV and SC treatment, males and females and pre-treatment and no pre-treatment. In high dose animals lower percentages of U1 were found and higher percentages of U3.

No TBHP was found in the exhaled air after IV treatment and small amounts after SC treatment. It was assumed that some TBHP leaked away from the SC injection site. 2-methylpropan-2-ol was the main metabolite in exhaled air accounting for approximately 97% of the material found. The other metabolite in exhaled air was not identified.

Within 15 minutes (first measurement) after IV injection no TBHP but mainly 2-methylpropan-2-ol was found in plasma. The 2-methylpropan-2-ol levels were steady for almost an hour and then quickly disappeared from the plasma. The metabolites P1, P2 and P3 (in the metabolite codes for the various matrices comparable numbers indicate the same retention time) increased and reached Tmax after 2, 8 and 2 hours, respectively. P2 was the main metabolite after 2 hours and the only one after 12 hours.

Also in plasma and tissues collected after 2 and 12 hours from male rats treated subcutaneously with 5 or 50 mg/kg bw, no TBHP was detected. At 2 hours, 2-methylpropan-2-ol was the main metabolite in all tested tissues accept for the liver where L3 was the main metabolite at 2 hours. Substantial amounts of K3 were also found in the kidney at this time point. At 12 hours, metabolite 2 was the only metabolite in all organs of the low dose animals and the main metabolite at the high dose. The results indicated saturation of metabolism at the high dose.

Acid hydrolyses of urine samples resulted in a strong decrease in U3 and a comparable increase in 2-methylpropan-2-ol indicating that U3 is a conjugate (probably the glucuronide or sulphate) of 2-methylpropan-2-ol. This is supported by the observation that U3 was mainly found in the liver and also in the kidney. 2-Methylpropan-2-ol was identified based on coelution. U2 co-eluted with 2-hydroxy-isobutyric acid, which is also a metabolite of 2-methylpropan-2-ol. U1 was not identified but based on literature data on the metabolism of 2-

methylpropan-2-ol it is postulated that this is 2-methyl-1,2-propanediol. The proposed metabolic pathway is that TBHP is converted to 2-methylpropan-2-ol which is either conjugated or further oxidised to 2-methyl-1,2-propanediol. 2-methyl-1,2-propanediol is oxidised to 2-hydroxyisobutyric acid probably via 2-hydroxyisobutyraldehyde.

No changes in total glutathione and GSSG were found in kidney and testes of high and low dosed rats at 2 and 36 hours after SC injection. A reduction of total GSH was found in the liver at 2 hours after SC injection with 50 mg/kg bw and an increase in total GSH at 36 hours.

#### Metabolism of 2-methylpropan-2-ol

The metabolism of 2-methylpropan-2-ol was studied in several species. The major metabolites identified with <sup>13</sup>C-NMR in the urine of rats (n=3) orally treated with 250 mg/kg bw <sup>13</sup>C-2-methylpropan-2-ol were tert-butyl sulfate, 2-hydroxyisobutyric acid and 2-methyl-1,2-propanediol. Minor metabolites were acetone and tert-butyl glucuronide. 2-Methylpropan-2-ol was found as a minor fraction in the urine (Bernauer *et al.*, 1998).

The major metabolites identified with <sup>13</sup>C-NMR in the urine of one male volunteer orally treated with 5 mg/kg bw <sup>13</sup>C-2-methylpropan-2-ol were 2-hydroxyisobutyric acid and 2-methyl-1,2-propanediol. Minor metabolites were 2-methylpropan-2-ol and tert-butyl glucuronide. Only a trace of tert-butyl sulfate was found (Bernauer *et al.*, 1998).

In the urine of untreated rats low amounts of 2-methylpropan-2-ol, 2-hydroxyisobutyric acid and 2-methyl-1,2-propanediol were found (Amberg *et al.*, 2000).

#### In vitro studies

Homogenates of stomach and small intestinal contents from two fasted and two non-fasted male Wistar rats (20 g) were diluted (1:4) and incubated with 100 mg [ $^{14}$ C]-TBHP at 37°C in wash bottles continuously flushed with nitrogen. The effluent gas was led through washing bottles to trap  $CO_2$  and volatile organic compounds. Samples were taken from the effluent and the incubation mixture at several time points up to 4 hours to determine the total amount of radioactivity, TBHP and metabolites.

Up to 45% of the applied amount of TBHP evaporated from the incubation bottles over 4 hours. Over 90% of the radioactivity remaining in the incubation mixture was TBHP, indicating that TBHP is reasonably stable in stomach and small intestine contents. No formation of 2-methylpropan-2-ol (tributyl alcohol) or other unknown metabolites was found after incubation with stomach contents. A small increase in 2-methylpropan-2-ol was found after incubation with small intestine contents (de Bie, 2003).

The percutaneous absorption was determined using an *in vitro* method with rat skin membranes according to OECD 428 (Maas, 2004). [<sup>14</sup>C]-TBHP (6.4 µl) was applied on top of the rat skin membranes (surface 0.64 cm², 0.6 mm thickness, non-fresh) in a flow-through diffusion cell. Concentrations of 1.0, 10.0 and 60% were used as these were considered relevant for workers. Exposure times were 1, 4 and 8 hours for 1.0 and 10% and 1, 2 and 4 hours for 60% using 4 membranes per group. A preliminary test with semi-occlusion demonstrated poor recovery. Therefore, the *in vitro* test was done using either a charcoal filter or glass slide to cover the exposure site. The receptor fluid was saline containing 0.01% azide

and 3% bovine serum albumin. The integrity of the membranes was checked using tritiated water. Receptor fluid samples were taken every hour and samples of all other materials at the end of the exposure period for radioactivity determination.

The mean total recovery of radioactivity was  $88 \pm 3\%$  for cells with a charcoal filter and  $81 \pm 9\%$  for cells with glass coverings. At 1 and 10% TBHP with charcoal covering penetration was seen without a lag time with maximal penetration between 0 and 2 hours. At the higher concentration with charcoal and all concentrations with glass slides, a short lag time of less than 1 hour was seen with maximal penetration between 1 and 3 hours. Strong differences in flux and Kp values were seen between the concentrations and coverings (**Table 4.3**). The total penetration of TBHP and/or metabolites (sum of radioactivity from receptor fluid, cell wash and skin membrane (total skin digest) as a percentage of the applied radioactivity) was constant after 1 hour for the 1.0% and 10% concentrations using the charcoal filter (**Table 4.4**). This might indicate that after 1 hour most TBHP was bound to the charcoal. Skin surface damage was often seen at the end of the exposure period especially with the higher dose levels and under occlusive conditions. The damage can explain the increase in penetration at higher concentrations and under occlusion.

Table 4.3 In vitro penetration parameters of TBHP (as total radioactivity)

|                                      |          |       |        | 1     |        |        |

Full thickness skin was obtained from untreated male Lac a mice, stored at  $4^{\circ}$ C and used within 2 hours (Timmins and Davis, 1993). Circular skin samples with a diameter of 5 mm were placed in custom-made EPR sample cells and treated with 2  $\mu$ l 0.05 - 1 M TBHP with or without pre-treatment with the spin trapping agent DMPO. Treatment with 0.1 M TBHP in acetone without a spin trapping agent resulted in the formation of the ascorbyl radical. A maximum level was found within 3 to 5 minutes after which the radical level was stable. The ascorbyl radical level increased dose dependently up to 0.25 M followed by a decrease that

can be explained by the oxidation of the ascorbyl radical to dehydroascorbate. The use of acetone as solvent compared to water and tape stripping of the skin resulted in an increase of the ascorbyl radical. This indicates that the reaction takes place below the surface of the skin. Incubations of skin samples pretreated with DMPO with TBHP resulted in EPR signals which were assigned to carbon centred and alkoxyl radicals based upon their hyperfine coupling constants and comparison with previous data. This indicates that "in vivo", one electron reduction is the main dermal metabolic pathway for radical formation from TBHP in mice.

#### Derivation of a dermal absorption figure based on the available data

No dermal absorption figure can be derived from the dermal *in vivo* study (de Bie, 2003) because of the low recovery in this study and possible co-exposure via inhalation as a result of evaporation. The mean total recoveries in the *in vitro* dermal absorption studies (Maas, 2004) were  $88 \pm 3\%$  and  $81 \pm 9\%$  for cells with a charcoal filter and for cells with glass coverings, respectively. These values are just below the minimum recovery as specified in OECD guideline 428 (90%). However, these values are considered acceptable as TBHP may evaporate to a relatively large extent. In these studies, the tested dermal area doses were 0.1, 1.0 and 6.0 mg/cm² (concentrations of 1%, 10% and 60% TBHP, respectively) under (semi-) occlusive conditions.

When establishing the dermal absorption figures which will be taken forward to the risk characterisation, the actual dermal exposure levels used in the risk characterisation should also be taken into consideration, as the percentage dermal absorption may depend amongst others on the dermal area dose (often being inversely related to the percentage absorption, see TGD, 2003, Appendix IV B Dermal absorption). The dermal exposure levels which are considered in the risk characterisation are 0.001-0.01 mg TBHP/cm<sup>2</sup> (occupational exposure scenario 3, contact with products containing <1% TBHP) and 0.032 mg TBHP/cm<sup>2</sup> (occupational exposure scenario 4, use of products containing <1% TBHP)) (see **Table 9.4** in section B.9.5).

The retrieved dermal absorption parameters for the lowest tested dermal area dose (0.1 mg/cm²) in the studies of Maas (2004) are relevant because this dermal area dose is comparable to the estimated dermal exposure loading of workers in occupational exposure scenario 4 (0.032 mg/cm²) and because the *in vitro* data do not show an inverse relationship between area dose and percentage absorption. Because it is not likely that occlusion will occur (contamination of hands in occupational exposure scenarios 3 and 4 is estimated assuming no gloves), the relative absorption parameters using a charcoal cover (semi-occlusive condition) are considered relevant.

In the studies by Maas (2004), skin damage was observed with the higher levels and under occlusive conditions (using a glass cover). At the level of 0.1 mg/cm² under semi-occlusive conditions, skin damage was not observed in the *in vitro* study. The comparable Kp-values retrieved from Maas' experiments for the dermal area doses of 0.1 mg/cm² and 1.0 mg/cm² in the presence of a charcoal cover showed that there was also no skin damage at a level of 1.0 mg/cm². Therefore, the absorption results from the dermal area dose of 0.1 mg/cm² can be used for the risk characterisation.

The total absorption (sum of radioactivity from receptor fluid, cell wash and skin membrane (total skin digest) as a percentage of the applied radioactivity) of TBHP using a charcoal cover at the dermal area dose of 0.1 mg/cm<sup>2</sup> was 3.5% after 8 hours. The relative absorption of the potentially absorbed amount of about 3.5% determined at 8 hours using a charcoal cover will be taken forward to the risk characterisation regarding occupational exposure scenario 4.

With respect to dermal exposure to products containing <1% TBHP in occupational scenario 3, the dermal exposure values are somewhat lower compared to the dermal exposure values in occupational exposure scenario 4. However, as in the study by Maas (2004) the absorption figures are comparable for the dermal area doses of 0.1 mg/cm² and 1.0 mg/cm² after 8 hours in the presence of a charcoal cover (see **Table 5.4**), it is expected that for a dermal area dose of 0.01 mg/cm² (estimated skin exposure level in scenario 3) a relative absorption figure comparable to that of the dermal area doses of 0.1 mg/cm² and 1.0 mg/cm² may be applicable. Therefore, 3.5% as dermal absorption value will also be taken forward to the risk characterization for this scenario.

#### 4.1.2 Human information

None

#### 4.1.3 Summary and discussion on toxicokinetics

The text below is a direct copy from the Summary of the toxicokinetics, metabolism and distribution, from the RAR of TBHP.

TBHP is stable in the stomach and intestine and completely absorbed after single and repeated SC and oral exposure at levels between 5 and 50 mg/kg bw. The absorbed TBHP is rapidly converted to 2-methylpropan-2-ol and distributed over the body. The significant reduction of GSH at 2 hours after exposure in liver is consistent with a first-pass metabolism. 2-Methylpropan-2-ol is either excreted in exhaled air, conjugated and eliminated in the urine or oxidised to and excreted in the urine as 2-methyl-1,2-propanediol and 2-hydroxyisobutyric acid (Figure 1). 2-hydroisobutyric acid was the main metabolite in all tissues at 12 hours after treatment. Female rats showed an increased metabolism resulting in lower tissue residues. The results at both dose levels were almost proportional but indicated some saturation of metabolism.

More specific in vivo and in vitro studies show that besides the major detoxification route TBHP can also form tertiair-butyl peroxyl radicals, tertiair-butoxyl radicals and carbon centered radicals. These radicals can react with many other molecules resulting in many different reaction products.

An oral absorption of 100% was determined for TBHP based on the comparable kinetic parameters after IV and SC exposure for total radioactivity, the high urinary excretion compared to the total recovery and the stability of TBHP in stomach and small intestine contents. However, the bioavailability (presence of substance in the systemic circulation) of

TBHP is very low or absent due to the reactivity of TBHP and the rapid conversion to 2-methylpropan-2-ol as shown by the absence of TBHP at 15 minutes after IV injection.

An increase in free radicals in some organs was observed by Ritchie et al. (2005a) after oral exposure but not after dermal exposure (Ritchie et al., 2005c). The increase in free radicals in the liver and blood after oral exposure is considered evidence of a local formation of free radicals. The increase in free radicals in the kidney could be interpreted as an indication of the presence of TBHP in the systemic circulation. However, it is unclear why this increase was not found in the heart or the lung. Overall, the information on the free radical formation from the studies by Ritchie et al., (2005a,c) are too limited to make a firm conclusion on the bioavailability of TBHP. The absence of systemic bioavailability, as observed in the i.v. study, is confirmed by the pattern of toxicology which showed only local toxicity and no systemic toxicity. Overall, systemic availability of TBHP and radical formation in organs beyond the site of first contact are not expected because of the corrosive properties of TBHP which will prevent such high exposures to occur.

No information on the inhalatory absorption is available. However, given the good absorption after oral exposure indicating good membrane diffusion, the good water solubility and high vapour pressure, 100% absorption after inhalatory exposure is expected and taken forward to the risk characterisation.

Based on the available in vitro dermal absorption study and taking into consideration the actual dermal exposure levels used in the risk characterisation, a dermal absorption value of 3.5% is taken forward to the risk characterisation for exposure without occlusion to products containing concentrations below 1% TBHP.

Not relevant.

#### 4.7.1.2 Repeated dose toxicity: inhalation

The studies summarised in this paragraph are inserted in this CLH report only for information and not for classification. The text below is copied from the Annex XV transitional report of TBHP.

In a 5-day range-finding inhalation study (Ma-Hock et al., 2010a), groups of 5 male rats (Wistar) per dose were exposed for 6 hours a day on 5 consecutive days to a vapour of TBHP. Additional groups of 5 male rats were treated the same way and were used for the Comet assay. The actual exposure levels were 0, 20, 91 and 179/377 mg TBHP/m³ (presented as 100% TBHP). These concentrations were generated by heating TBHP-70 containing 69.8% TBHP and dilution with air. The observations included: clinical observations, body weight, Comet assay under alkaline conditions in lung cells (control and high dose only), FACS analyses of the type of cells present in the isolated lung cells (control and high dose only), gross pathology, organ weight for a limited number of organs and histopathological examination of the respiratory tract, thymus and adrenals.

Two animals out of 10 in the highest dose group died during the exposure period (on day 1 and day 2). The exposure concentration in the highest dose group was therefore reduced from 377 mg/m³ to 179 mg/m³ for the remaining treatment period. The animals in the highest dose group showed abdominal respiration, apathy, eyelid closure of both eyes, gasping, labored respiration, red nose crust formation, piloerection and respiration sounds on all exposure days. The body weight of the animals in the highest dose group was significantly reduced on day 4. Body weight gain was significantly reduced in the intermediate and high dose group. The absolute and relative lung weight in the intermediate dose group, were significantly reduced whereas the relative lung weight in the high dose group was significantly increased. The

adrenal weight showed a dose related increase (absolute and relative) which was significant at the high dose. The thymus weight was dose dependently reduced (absolute and relative) which was significant for the high dose group. Histopathological changes were observed in the nasal cavity, the larynx and the trachea in the mid and high dose group. The severity of the effects was the highest in the upper parts of the respiratory tract and decreased towards the lower parts. Changes in the lung bronchi on the bronchiolar epithelium were observed in 3 out of 6 animals of the high dose group. Bronchiolar necrosis was observed in one animal and two others showed hyperplasia of the bronchiolar epithelium. In the adrenal cortex fatty change (lipid-like vacuoles within the cytoplasm) was observed in one animal of the mid dose and three animals of the high dose group. In the thymus, a decrease of the cellular density of the cortex and an increase in starry sky cells (macrophages containing apoptic lymphocytes within the cytoplasm) were present in three out of five animals of the high and mid dose group and one animal of the low dose group. The Comet assay in lung cells showed comparable values for tail moment, length and relative intensity for the high dose group (n=4) and the control group (n=5). The FACS analyses for the type of cells present in the long cell suspension was limited to three animals in the control group and two animals in the high dose group. Apparently not all parameters could be determined for these animals (the part on FACS analyses was only limitedly described in the report). The results indicate an increase in CD45-positive cell stated as meaning leukocytes from the blood or interstitial space or free lung cells in the high dose group compared to the controls. This also means a reduction in the percentage of epithelial and endothelial cells in the lung cell preparation. There was no increase of CD11 positive cells indicating no relevant inflammation occurred in the lung.

Based on the absence of effects at 20 mg/m<sup>3</sup> and several effects at 91 mg/m<sup>3</sup>, including histopathological changes in the respiratory tract indicative of respiratory tract irritation, target dose levels of 7.4, 22.2 and 77.7 mg/m<sup>3</sup> were chosen for the 28-day inhalation study.

In a subacute inhalation study (Ma-Hock et al., 2010b), groups of 6 rats (Wistar) per sex and dose were exposed for 6 hours a day, 5 days a week for in total 28 treatment days to a vapour of TBHP. The actual exposure levels were 0, 7.2, 22.6 and 67.0 mg TBHP/m³ (presented as 100% TBHP). These concentrations were generated by heating TBHP-70 containing 69.8% TBHP and dilution with air. The study was performed according to OECD 412 and B.8 of the EU Test Method Regulation (EC 440/2008), according to GLP and including extensive histopathology of the nasal cavity, larynx and lungs and cell proliferation at two sites of level I of the nasal cavity. The choice of the exposure levels was based on a 5 day range finding study in male rats which showed mortality and irritation of the upper respiratory tract at 179/377 mg/m³, moderate irritation at 91 mg/m³ and no adverse effects at 20 mg/m³.

No deaths were recorded throughout the study. Body weight and body weight gain were reduced in the males at the highest dose on day 7 and day 14 (Table 4.6). A reduction in relative kidney weights was observed in all treated females compared to the controls. Although this decrease was statistically significant in the mid and high dose groups, the decrease was less than 10%, there was no dose response relationship and there were no histopathological findings that could explain the weight reduction. Therefore, this effect is considered to have no biological significance. An increase in hyperplasia/metaplasia of the transitional epithelium in nasal cavity level 1 sections was observed in 5 males and 3 females at the high dose level. This occurred mainly at the tip of the maxilloturbinate and the lateral wall of the nasal cavity as a minimal to mild increase in thickness of the transitional epithelium and a slight change towards squamous epithelium. The unit length labelling index (ULLI) of the affected regions of the maxilloturbinate and the lateral wall, measured as the incorporation of BrdU, was increased in males and females at the highest dose. A slight but

significant increase in ULLI of the affected regions of the maxilloturbinate was also observed in males at the mid dose. An increase in ULLI indicates an increase in the proportion of cells undergoing replicative DNA synthesis. The increase in the males at the mid dose was not considered substance related by the study author because it was minimal (1.5-fold) and mainly caused by a single animal. In our opinion this effect is probably substances related because there was a dose response relationship and because the increase was statistically significant. No histopathological changes were observed in other organs including the larynx and the lung.

An overall NOAEC of 7.2 mg/m<sup>3</sup> is derived from this study based on an increase in ULLI in males at a dose level of 22.6 mg/m<sup>3</sup> (LOAEC).

No increase in lung cell DNA damage was observed in the Comet assay at the highest dose tested compared to the control group. Changes of the bronchiolar epithelium were observed in some animals of the high dose group. The absence of DNA damage at a dose level inducing some bronchiolar epithelial changes may indicate that TBHP at this dose level does not induce local DNA damage in the lung detectable with the Comet assay. However, it can not be excluded that possible DNA damage to bronchiolar epithelium was diluted by the presence of other cell types not affected by TBHP. An increase in other cell types in the high dose group was indicated by the FACS analyses.

No information was provided regarding DNA damage in the upper respiratory tract where the most severe toxicological effects were observed. Determination of DNA damage in nasal and bronchial epithelial cells was not possible in the COMET assay using the techniques described in the feasibility study (Schulz, 2009).

#### 4.8 Germ cell mutagenicity (Mutagenicity)

The information in this chapter is based on the RAR of TBHP plus the additional information available in the transitional report. The information in the RAR was available for the TC-C&L in their discussion in 2006 and 2007 (see Annex A and B). However, the information from the transitional report was not available for the TC-C&L. The main additional information regarding mutagenicity in the transitional report is the Comet assay in the lung.

The results of available genotoxicity studies are summarized in Table 4.7 for *in vitro* prokaryotic test systems, Table 4.8 for *in vitro* eukaryotic test systems, Table 4.9 for *in vivo* genotoxicity tests with insects, and Table 4.10 for *in vivo* genotoxicity tests with mammals.

<sup>\*</sup> purity of TBHP not specified

#### 4.8.1 Non-human information

#### 4.8.1.1 *In vitro* data

In prokaryotic cells TBHP causes gene mutations (Haworth *et al.*, 1981; Haworth *et al.*,1983; Yamaguchi and Yamashita, 1980, Ryden *et al.*, 2000, Blanco *et al.*, 1995, Blanco *et al.*, 1998, Minnunni *et al.*, 1992, Kranendonk *et al.*, 1996, Watanabe et al., 1998; Ohta *et al.*, 2000) and DNA damage (Epe *et al.*, 1990; Mersch-Sundermann *et al.*, 1994; von der Hude *et al.*, 1988; Kato *et al.*; 1994, Nunoshiba and Nishioka, 1991, Muller and Janz, 1992).

In eukaryotic cells TBHP can induce gene mutations (Callen & Larson, 1978; Zimmermann *et al.*, 1984; Dickey *et al.*, 1949; Brockman *et al.*, 1984; Kirby *et al.*, 1981), chromosomal aberrations (Ochi, 1989; de Vogel, 1992) and changes in chromosome number (Önfelt, 1987). Also, TBHP can induce DNA strand breaks (Lee *et al.*, 2004) and DNA fragmentation (Latour *et al.*, 1995) in *in vitro* test systems.

In the study of Altman *et al.* (1994) treatment of mammalian cells with low concentrations of TBHP resulted in DNA base damage. However, high concentrations of TBHP inhibited DNA base damage. The authors suggest that this may be the result from scavenging of the intermediate tert-butoxyl radical by TBHP giving rise to the formation of tert.-butyl peroxyl radical which is further oxidized. It indicates that TBHP exposure by itself may not directly cause the DNA base damage. Hazlewood and Davies (1995) showed with the technique of EPR spin trapping that the tert-butoxyl radical generated from TBHP is capable of damaging DNA and RNA *in vitro*.

TBHP did not induce cell transformations in Chinese hamster cells (Thilagar et al., 1981).

#### 4.8.1.2 *In vivo* data

#### Insects

Genotoxicity studies with Drosophila melanogaster indicate that TBHP *in vivo* can induce lethal mutations after exposure of the eggs to the vapour or dilutions of TBHP, but no mutagenic effect was detected when the males were treated in the adult stage (Altenburg, 1954). Sex–linked recessive lethal mutations in germ cells of Drosophila melanogaster after injection of the adults with TBHP indicate that TBHP can have a genetic effect (Woodruff et al., 1985). Also a mutagenic effect was found in the w/w+ SMART assay after oral exposure to toxic and highly toxic dose levels (Gaivao *et al.*, 1999).

#### Mammals

Fasted male Wistar rats (n=2-3 but not clearly stated) were treated by gavage with a single dose of TBHP (70%) at 1 ml/kg bw (approximately 700 mg/kg bw). The rats were sacrificed after 4 hours and samples of liver and stomach were collected for DNA isolation and analysis of 7-methylguanine and 8-methylguanine using HPLC with UV and electrochemical detection after acid hydrolysis. The 7-methylguanine levels in the stomach (135±15 ug/g guanine) were significantly increased compared to control rats (n=3)( 85±10 ug/g guanine). No significant increase was found in the liver (n=2). 8-methylguanine was not detectable in the liver and stomach from control

animals. In treated rats, the 8-methylguanine level was higher in liver (63 ug/g guanine) compared to stomach (35±7 ug/g guanine) (Hix *et al.*, 2000). Other tissues were not tested. It should be noted that this is a very high dose, exceeding the oral LD50.

Groups of 6 male Fisher rats received a single subcutaneous injection with TBHP at a dose of 117 mg/kg bw (Farombi *et al.*, 2004). The rats were sacrificed at 2 hours after injection. The Comet assay was performed on liver cells using no enzymatic digestion, digestion with endonuclease III to determine oxidized pyrimidines and digestion with formamidopyrimidine glycosylase to determine altered purines including 8-oxo guanine. No increase in tail DNA was seen with or without digestion of the liver cells. Effects on other parameters, namely increases in 2-amino adipic semialdehyde (a biomarker of protein oxidation) and malondialdehyde (a biomarker of lipid peroxidation) in liver, indicated that the TBHP had reached the liver. Numerical values are not available (only figures).

A bone marrow micronucleus test described by van Delft and de Vogel (1995) was performed according to OECD 474 guideline. Male and female Swiss mice (fifteen/sex/dose) were given a single intravenous dose of 100 mg/kg bw TBHP in saline, the maximum tolerated dose as determined in an earlier range-finding study. Intravenous injection of TBHP should result in adequate exposure of the bone marrow target cells. At 24, 48, and 72 hours after treatment, ten vehicle controls (five/sex) and ten test-animals (five/sex) were sacrificed. PCE:NCE ratios were not statistically significantly different in male mice treated with 70% TBHP than those found in vehicle controls. In female mice at 48 and 72 hours sacrifice times the PCE:NCE ratios were weakly significantly higher than those found in controls. At all sacrifice times, the incidences of micronucleated polychromatic erythrocytes per 1000 polychromatic erythrocytes in mice treated with TBHP were not increased, indicating that an intravenous injection of 100 mg/kg bw TBHP did not result in chromosomal damage and/or damage to the mitotic apparatus in bone marrow cells of mice.

In a bone marrow test described by Ben-Dyke and Hogan (1981) rats were exposed for five days to TBHP by inhalation (0, 33, 111, 273, and 347 mg/m³ 100% TBHP). Cytotoxicity of bone marrow cells was measured after exposure of the animals to 369 mg/m³ 100% TBHP using the mitotic index: in female rats the mitotic index increased from 2.2% after exposure to untreated air to 3.7% after exposure to 369 mg/m³ 100% TBHP, whereas in male rats a decrease was observed of 3.5% (control) to 2.8% (369 mg/m³ 100% TBHP). TBHP (up to and including 347 mg/m³ 100% TBHP) did not induce any chromosomal aberrations in rats of either sex.

A third bone marrow test is described by Katosova (1978). It should be noted that only a translation of this study is available and the description of the methodology and results are very limited. Mongrel albino male rats (no group sizes given) were exposed by inhalation to a single concentration of 118 or 360 mg/m³ TBHP, the latter stated by the authors as the toxic action threshold (purity of TBHP not specified). Another group of male mongrel albino rats were exposed by inhalation for a longer term (2.5 or 4 months) to 0 or 17 mg/m³ TBHP (stated by the authors as chronic action threshold) or 107 mg/m³ TBHP. In addition to the effects on chromosome aberrations the gonadal functions were studied. No effects of TBHP on spermatogenesis were observed but the findings were not substantiated by any numerical data. An increased number of chromosomal aberrations was found in rats exposed to the highest concentration of TBHP both after 2.5 months (4.6, 4.5, 9.0% cells with aberrations for the control, 17 and 107 mg/m³ TBHP, respectively) and 4 months (5.0, 5.4, and 8.5% cells with aberrations for control, 17 and 107 mg/m³ TBHP, respectively). Given the rapid metabolism of TBHP, the pattern of results obtained appears implausible. No details of general toxicity are given. Because of the fact that this study deviates

markedly from the OECD guideline 474, and the poor description of the methodology and results, the rapporteur considers this study as not valuable for risk assessment.

In a dominant lethal study (Kumar and Muralidhara, 1999) male Swiss mice were given intraperitoneal 300 μmol/kg bw for five days (= 27 mg/kg bw/day 100% TBHP, which is 1/10th of the determined LD<sub>50</sub>-value in this study (see section 5.2.1). Fifteen males from each treatment group were mated with virgin females (1:2) each week sequentially for a period of 8 weeks. Successful mating was ascertained by the presence of vaginal plugs and all the pregnant females were killed 16-17 days thereafter. The percentage of induced pregnancies ranged from 83.3-100% (for TBHP and the positive control ethyl methane sulphonate) and was comparable to those of negative controls. Total number of implantations per male was similar after treatment with TBHP. A statistically significant decrease was found in the number of live embryos resulting from TBHP treated male mice during the first 4 weeks, and it normalized at week 5. TBHP treated males produced a 3- and 2-fold increase in dead implantations (DI) during the first and second week, respectively. Nearly a 4-fold increase of DI was observed during the third and fourth week compared to the control group. The numerical percentage of dominant lethality for week 1 to 5 were 8.6%, 8.6%, 11.3%, 8.5% and 8.5% for controls and 23.1%, 18.5%, 50.0%, 37.5% and 11.5% for TBHP. This was statistically significant from week 1 to 4 (p<0.001).

In a follow-up of the dominant lethal study by Kumar and Muralidhara (1999), male Swiss mice were given intraperitoneal 300 or 600 μmol/kg bw for five days (= 27 or 54 mg/kg bw/day 100% TBHP) or 150, 300 or 600 µmol/kg bw for one day (Kumar et al., 2002). Samples from testis and epididymal sperm were collected at 24 hour and 1, 2, 3 and 5 weeks after treatment. Males with repeated exposure were mated with untreated females for one week during five weeks. No effects were found on mortality, clinical toxicity, body weight, testis weight and testis histopathology at 1, 2, 3 and 5 weeks after repeated exposure. No or only a marginal increase in lipid peroxidation, as measured by the formation of thiobarbituric acid reactive substances, in testis and epididymal sperm cells was found at 24 hours. However, an increase in lipid peroxidation of approximately 30 to 40% was found at 24 hours and 1 week after repeated exposure at both dose levels. An increase of 15 to 20% was seen in week 2 and levels returned to control levels on week 3 and week 5. The percentage double stranded DNA measured using the fluorimatic analysis of DNA unwinding, was decreased in the testis at both dose levels at 2 hours after repeated exposure. In epididymal sperms, this effect was only seen at the highest dose. Caudal sperm counts were not affected by repeated treatment but an increase in abnormal sperms was seen during the first 3 weeks followed by a normalisation at week 5. Repeated treatment at both dose levels resulted in a 20-30% decrease in pups/litter after mating during the first three weeks but not in week 4 and 5. No numerical values available.

This study was recently followed by a study on the underlying biochemical mechanisms for the effects on the testis (Kumar and Muralidhara, 2007). However, in this study rats were used instead of mice. Groups of 4 male CFT-Wistar rats received a single intraperitoneal injection with 0, 6.8, 13.5 or 27 mg/kg bw TBHP. The rats were killed at 24 hours after exposure. In a second experiment, the male rats (n=4) were exposed daily to the same dose levels for 1 or 2 weeks. The rats were killed at 24 hours or 1 or 2 weeks after treatment. Single and repeated treatment did not induce mortality, clinical effects, body weight effects or testis weight effects. Also no histopathological changes were found in the testis and epididymis. Caudal sperm counts were significantly decreased at the highest dose level after 2 weeks of treatment. A single exposure did not affect the malondialdehyde level (MDA, a marker for lipid peroxidation) nor reactive Oxygen Species (ROS) in the testis. However, repeated exposure for 1 or 2 weeks induced a dose and

exposure duration dependent increase in MDA and ROS which were significant from 13.5 mg/kg bw. Comparable effects on both parameters were seen in epididymal sperms. The increase in ROS was also significant at the lowest dose after 2 weeks of exposure. The protein carbonyl and iron content of the testis was increased from 13.5 mg/kg bw after two weeks of exposure. The non-enzymatic antioxidant levels in the testis (GSH, ascorbic acid and alpha-tocopherol) were reduced. The reduction was significant at 13.5 mg/kg bw/day for ascorbic acid and alpha-tocopherol and at 27 mg/kg bw/day for GSH. The activity of 3 out of 5 tested antioxidant enzymes in the testis (GPX, GST and CAT) was increased after 2 weeks of treatment. The activity of GR(not specified) was reduced. The changes were significant for some endpoints already at the lowest dose level. The SOD activity was not affected. The activity of four different dehydrogenases (LDH-x, SDH, G6PDH and ICDH) was significantly increased at the highest dose level. The percentage of dsDNA, as determined by fluorimetric analysis of DNA unwinding, in testis and epididymal sperm showed a dose dependent decrease which was significant from 13.5 mg/kg bw/day, indicating increased strand breaks.

This study indicates that oxidative stress and DNA effects can occur after TBHP exposure to levels which also induce a change in some but not all enzymatic and non-enzymatic antioxidants. However, some effects like an increase of ROS and an increase in antioxidant enzyme activity were found at levels without a reduction in non-enzymatic antioxidant levels. These effects were seen at levels which did not induce effects on testis weight or testis histopathology.

A dominant lethal test is described by Katosova (1978). It should be noted that only a translation of this study is available and the description of the data is very limited. Male tetrahybrid mice (n=20/dose) were exposed by inhalation to 2, 17, or 107 mg/m³ TBHP (purity not specified) for two months, and mated with females. Incidence of pregnancies, total implantations and live embryos were determined. Number of pregnant females was 70 for the control group and 60 for each exposed group. The study authors state that in the group treated with 17 mg/m³ TBHP the embryonal mortality before implantation was increased (but not the embryonal mortality after implantation), and an exposure of 107 mg/m³ increased the postimplantation mortality of the embryos. However, the results given in the additional table could not be derived from the available raw data. The rapporteur considers this study not valuable for risk assessment.

In another dominant lethal study (Epstein et al., 1972), male ICR/Ha Swiss mice received a single intraperitoneal injection with subtoxic concentrations of 15 mg/kg bw (n=7) or 75 mg/kg bw (n=9) TBHP (purity not specified), and were subsequently caged with 3 untreated females, which were replaced weekly for 8 consecutive weeks. Females were sacrificed 13 days after the midweek of their caging, without being checked for vaginal plugs. The study authors report that no differences were observed in early foetal deaths and preimplantation losses, but no data are given.

Another study on the biochemical mechanism of the effects of TBHP on the testis was performed by Kaur *et al.* (2006). Male balb/c mice (n=6) were treated i.p. with a dose of 76 mg/kg bw/day (dosimetry confirmed by study authors in written correspondence) for 2 weeks and killed or bred to normal dams. Treatment significantly reduced the percentage of dams giving birth by 50% and the litter size in any dam giving birth as were epididymal sperm count and sperm motility. Lipid peroxidation (MDA) was significantly induced as were the enzyme activities for GSH-Px, GST and SOD. RNA levels, determined with PCR, of the stress related transcription factor NF-κB and of the anti-oxidant enzymes were increased. It is speculated that the effect on the sperm cells is directly or indirectly regulated by NF-κB. It is unclear whether the reduced fertility is due to a mutagenic

effect (resulting in non-viable embryos) or a direct effect on fertility (killing of sperm cells, resulting in no embryos at all) as no information on number of implantation sites was available.

The possibility of determining DNA damage via the COMET assay in nasal epithelium and epithelium of the upper airways was determined in a feasibility study by Schulz (2009). The technique used for cell isolation was based on several procedures described in the public literature. The epithelial layer was scraped from the nasal turbinates and septum and from the trachea using a scalpel. The collected tissues were incubated with residual turbinates and septum or trachea in several digesting enzymes. Only a small number of viable cells could be recovered from trachea. For nasal epithelium approximately  $1 - 3.5 * 10^6$  viable cells could be isolated per rat. Single cell gel electrophoresis under alkaline conditions of nasal epithelial cells of untreated rats showed a limited percentage of cells with intact DNA. Approximately 44-49% Hedgehog cells were observed in the isolations with the highest viability of approximately 80%. The tail intensities of the non-Hedgehog cells were high and exceeded the expected values for tissue preparations from untreated animals. The values were in the range normally associated with positive controls. Therefore, it was concluded that it is not possible to isolate good quality cells from nasal epithelium and trachea of the rat for the performance of the COMET assay.

The COMET assay on lung tissues of rats exposed to TBHP via inhalation showed no increase in tail moment, length and relative intensity (see summary in 4.7.1.2). However, the main effects were observed in the upper respiratory tract with no changes at the alveolar level and some bronchiolar changes. This indicates that only a limited part of the TBHP reached the lower respiratory tract. The absence of effects in the Comet assay may therefore be caused by the very limited exposure and dilution of possible genotoxic effects with unaffected tissues. The Comet assay could not be performed using epithelial tissues from the nose and upper airways due to technical problems.

#### 4.8.2 Human information

#### 4.8.3 Other relevant information: read-across

The substance di-tert-butyl-peroxide (DTBP) has been discussed for harmonised classification with with Muta. Cat 3; R68 by the RAC. RAC concluded that classification as Muta Cat. 3; R68 was justified based on clear positive results in two well conducted *in vivo* micronucleus assays (RAC opinion 2010). It is assumed that the mutagenicity of DTBP is caused via the formation of radicals from DTBP. Radical formation from DTBP can occur by splitting the electronic bond between the two oxygen atoms or by splitting the bond between one oxygen atom and the carbon atom. The same radicals plus other radicals can be formed from TBHP (see figure 2). As all radicals that can be formed from DTBP can also be formed from TBHP, it can be assumed that TBHP can also induce mutagenicity. The absence of a positive result in the *in vivo* micronucleus assay with TBHP seems to contradict this conclusion. However, as TBHP is very unstable it probably cannot reach the bone marrow to induce micronuclei as the probably more stable DTBP can. However, TBHP is expected to have the same mutagenic effect as DTBP in cells which can be reached by TBHP.

Figure 2 Possible radicals of TBHP and DTBP

## 4.8.4 Summary and discussion of mutagenicity

Based on the positive effects in the bacteriological gene mutation tests, a positive result in a  $tk^{+/-}$  assay with mammalian cells, and the fact that TBHP induces chromosomal aberrations and aneuploidy it is concluded that TBHP is mutagenic *in vitro*. Moreover, the fact that TBHP induces DNA base damage and DNA fragmentation indicates that TBHP is genotoxic *in vitro*.

The data set on genotoxicity of TBHP *in vivo* towards somatic cells is limited. Consequently, it is difficult to reach a conclusion on the genotoxicity *in vivo* of TBHP. The available *in vivo* studies indicate that TBHP induces DNA adducts in the liver and stomach after oral exposure to a dose exceeding the oral LD50. Since lower dose levels were not tested it is impossible to make a

statement on this effect at lower levels. Therefore, the worst case assumption is made that mutagenicity will occur at all dose levels including the levels to which humans are exposed.

Other *in vivo* data show that TBHP does not induce chromosomal aberrations in bone marrow *in vivo* and was negative in several other tests on the bone marrow as well. A limited Comet assay in rat liver after subcutaneous exposure was negative.

TBHP induces dominant and recessive lethal mutations in Drosophila when eggs are exposed or adults are injected, but no mutagenic activity is detected in adults upon oral exposure or exposure by inhalation. TBHP is positive in a dominant lethal assay in mice after intraperitoneal exposure and induces changes in sperm morphology. Comparable effects on fertility were found in additional tests on rats and mice after intraperitoneal exposure. This could be a local effect of TBHP on the testis because substances can migrate from the abdominal cavity through the inguinal channel to the testis.

The substance di-tert-butyl-peroxide (DTBP) was shown to be mutagenic to the bone marrow in an *in vivo* assay. As DTBP forms only radicals also formed by TBHP, it is likely that TBHP is also mutagenic.

The ADME study (de Bie and Grossouw, 2004, see paragraph 4.1.1) shows that TBHP is rapidly converted *in vivo* to 2-methylpropan-2-ol. After intravenous injection, no TBHP but mainly 2-methylpropan-2-ol was found in blood at the earliest measurement of 15 minutes after injection. Also after subcutaneous injection, no TBHP but mainly 2-methylpropan-2-ol was found in blood and tissues at the earliest measurement of 2 hours after injection. Based on the rapid conversion of TBHP to 2-methylpropan-2-ol after parenteral administration, no detectable levels of TBHP will also be expected after oral, dermal and inhalatory exposure due to the slower absorption and the first pass effect in the liver after oral exposure. 2-Methylpropan-2-ol was tested for mutagenicity by the NTP in 1995 and all *in vitro* and *in vivo* results were negative.

As mentioned above, TBHP is clearly genotoxic and mutagenic *in vitro*. TBHP was negative in several mutagenicity tests in the bone marrow. However, seen the rapid conversion of TBHP to the non-mutagenic compound 2-methylpropan-2-ol, it is very likely that TBHP did not reach the bone marrow. There are no local mutagenicity tests with TBHP available. TBHP is mutagenic in germ cells after *in vivo* exposure (changes in sperm morphology and an increase in dominant lethal mutations) after intraperitoneal exposure. This positive rodent dominant lethal mutation test would normally fulfil the criteria for classification in category 1B. The *in vivo* mutagenicity of TBHP is confirmed by the positive *in vivo* results with DTBP. However, it is unlikely that TBHP will reach the gonads through relevant routes of exposure in view of the rapid conversion to 2-methylpropan-2-ol. Therefore, the positive results of these germ cell tests are considered evidence for a local mutagenic effect. Consequently, the *in vivo* mutagenicity of TBHP through relevant routes is likely limited to somatic cells in the tissues of first contact and could possibly result in local carcinogenicity. The conclusion is that TBHP is mutagenic. However, as TBHP will not reach the germ cells after oral, inhalation and dermal exposure, exposure to TBHP is unlikely to result in inheritable genetic damage.

The mutagenic effects of TBHP are probably due to the formation of TBHP-derived radicals after one-electron oxidation or one-electron reduction and their reaction with DNA. This mechanism would theoretically lead to no threshold for the mutagenicity. However, radical formation and their reaction with DNA will probably depend on the antioxidant levels of the cell, with an increase in DNA adducts at TBHP levels which induce a reduction in the antioxidant levels. This would indicate a sub-linear dose-effect relation but could also indicate a threshold. No information is available on the dose-effect relation within the sites of first contact. A study to determine the

feasibility of the COMET assay to detect genotoxicity in epithelial cells of the nose and trachea showed that it is not possible to isolate good quality cells. The available studies on the testis after intraperitoneal exposure indicate that DNA effects were found at or around TBHP levels which also reduce the antioxidant level but at levels without histological changes. However, an increase in ROS and the activity of enzymatic antioxidants (which can be seen as secondary to the increase in ROS) was found at levels without a decrease in non-enzymatic antioxidants like GHS. The limited studies on the testis do not provide sufficient evidence that the formation of free radicals and possible DNA effects including mutations cannot occur at levels without a reduction in non-enzymatic antioxidants, nor do the *in vivo* metabolism data (e.g. de Bie and Grossouw (2004)) exclude the occurrence of radical formation before glutathione is depleted. Further, no information is available on the extrapolation to other tissues including the sites of first contact. Based on the available data it is assumed that TBHP is a non-threshold mutagen.

#### 4.8.5 Comparison with criteria

Classification with Muta 1A; H340 is not justified as there are no human data. Classification with Muta 1B; H340 could be considered as TBHP is positive in a rodent dominant lethal mutagenicity test. However, this test was positive after intraperitoneal exposure whereas the kinetic data show that TBHP does not reach the systemic circulation, and thus does not reach germ cells, after oral, inhalation and dermal exposure. Classification with Muta 1B; H340 is not justified because TBHP will not induce germ cell mutagenicity via normal routes of exposure. However, classification with Muta 2; H341 is proposed because it is shown in the dominant lethal mutagenicity test that TBHP is mutagenic to cells with which it comes into direct contact. Classification of local mutagens as Cat 2 is also in line with the guidance in chapter 3.5.1 of the Guidance on the application of Regulation (EC) No 1272/2008. Classification with Muta Cat. 3; R68 was recommended by the TC-C&L.

#### 4.8.6 Conclusions on classification and labelling

TBHP is a mutagen. However, the substance will only be mutagenic at the sites of first contact in somatic cells. Classification with Muta. 2; H341 (CLP) is proposed.

#### RAC evaluation of germ cell mutagenicity

#### Summary of the Dossier submitter's proposal

Tert-butyl hydroperoxide (TBHP) is positive in several *in vitro* studies. The *in vivo* dataset is limited and in most studies negative. However, TBHP is positive in a dominant lethal assay in mice after intraperitoneal exposure. This is considered as evidence for a local mutagenic effect of TBHP because substances can migrate from the abdominal cavity through the inguinal channel to the testis. However, TBHP has been shown to be unstable in blood in *in vivo* absorbtion, distribution, metabolism and excretion (ADME) studies. Therefore, it is unlikely that TBHP will reach the testis after exposure via normal routes. TBHP is therefore considered a local mutagen fulfilling the requirements for Muta 2.

Additionally, the dossier submitter (DS) noted that a similar substance, di-tert-butyl peroxide (DTBP), was shown to be mutagenic to the bone marrow in an *in vivo* assay. As DTBP forms only radicals which are also formed by TBHP, it is likely that TBHP is also mutagenic.

#### Comments received during public consultation

During public consultation, two MSCAs and one industry organisation agreed with the proposed classification.

One MSCA suggested that the statement in the proposal that TBHP is very likely not to be

systemically available could be more appropriately replaced with a statement that there is no data demonstrating that TBHP is systemically available.

In response, the DS argued against this suggestion as there is extensive kinetic data available in the CLH proposal which allow an assessment of the systemic availability.

Three industries raised the issue that using the DTBP data as a basis for harmonisation is not appropriate, and is not in line with ECHA's own guidance.

In response, the DS agreed that the justification for the read-across of the mutagenic properties from DTBP to TBHP is limited and does not follow the ECHA guidance on read-across. However, the DS considered this only as supportive information and for that reason did not include this in the comparison with the criteria. The DS also claimed that the information provided on the mutagenicity of both substances shows differences in the results in comparable tests indicating that there are differences in the mutagenic profile. According to the DS, classification of TBHP, solely based on read-across from DTBP is not justified. However, the fact that DTBP is also positive in *in vivo* mutagencity tests is considered supportive given the structural similarity. As both substances are used for the generation of radicals and the main metabolite of both substances, 2-methylpropan-2-ol, is not mutagenic, it is considered likely that both substances induce mutagenicity via the formation of radicals, although this has not not shown for DTBP.

Overall, the DS considers the observed mutagenicity of DTBP *in vivo* as supportive for the classification of TBHP for mutagenicity.

#### **Additional key elements**

In vitro, numerous studies consistently show that TBHP induces gene mutation in bacteria. In mammalian cells, induction of gene mutations was observed in a mouse lymphoma assay (MLA) assay similar to test guideline EU B.17 and induction of chromosomal aberrations was seen in two studies following, or similar to, OECD test guideline 473. Aneuploïdy, DNA fragmentation and DNA strand breaks (Comet assay) were also observed. Most tests were performed without metabolic activation but tests performed with metabolic activation also gave positive results (gene mutation in bacteria and mammalian cells, chromosomal aberrations in mammalian cells). TBHP was negative in a transformation assay. Overall, the clastogenic and mutagenic effects of TBHP are well established *in vitro*.

In vivo, genotoxicity studies with *Drosophila melanogaster* indicate that TBHP can induce dominant or recessive lethal mutations after exposure of the eggs to the vapours or to dilutions of TBHP and after exposure of adults to oral toxic doses or by injection. But no mutagenic effect was detected when the males were exposed in the adult stage to vapour or orally at doses not reported as toxic.

In mammals, studies performed in somatic cells at distant sites of exposure are summarised in table 1 below. Although DNA adducts were detected in the stomach and liver in rat at a very high oral dose, no effect were observed on DNA breaks (Comet assay) in liver cells further to subcutaneous exposure, on micronucleus in the bone marrow in mice after intravenous (IV) exposure or on chromosomal aberrations in the bone marrow in rats after repeated (5-day) inhalation exposure.

In the Comet assay, the micronucleus and the chromosomal aberration assay it is noted that some evidence support that the target organs were reached by TBHP or its metabolite(s). Overall, there is no evidence of genotoxicity from *in vivo* studies performed on somatic cells distant from exposure site.

Table 1 – In vivo studies in somatic cells distant from exposure site

One study investigated the genotoxic potential of TBHP at the site of contact: a Comet assay was performed in the lung tissue of rats further to a 5-day repeated exposure via inhalation (see experimental conditions in table 2 below) and gave a negative result. It is however noted

that in this study, histopathological changes were observed in the nasal cavity, the larynx and the trachea in the mid- and high-dose group. The severity of the effects was the highest in the upper parts of the respiratory tract and decreased towards the lower parts. This indicate that only a limited part of the TBHP reached the lower respiratory tract and the negative result in the lung may be caused by dilution.

An attempt to perform a Comet assay on nasal and trachea epithelium was made in a feasibility study but either a small number of viable cells could be recovered (trachea) or values obtained in negative controls were similar to values in positive controls. It was concluded that it is not possible to isolate good quality cells from nasal epithelium and trachea of the rat to perform a Comet assay in these tissues.

Table 2 – In vivo studies in somatic cells at the site of exposure

Studies performed in germinal cells are summarised in table 3 below. The induction of dominant lethal mutations was detected in mice in two independent OECD-guideline studies performed in the same laboratory. These results were supported by observation of a decrease in double-strand DNA (indicative of an increase in strand breaks) in sperm of mice and rats and of an increase in abnormal sperm in mice. All results were obtained after repeated exposure by intraperitoneal (IP) route. After a single IP exposure in mice, a negative result was obtained in a dominant lethal mutation assay but the study was insufficiently reported to assess robustness of this result.

Overall, available data shows that TBHP induces mutations in germinal cells by IP route.

#### Additional data on toxicokinetic and possible read-across

The ADME study (de Bie, 2004) shows that TBHP is rapidly converted *in vivo* by reduction to 2-methylpropan-2-ol. After a single IV injection, no TBHP but mainly 2-methylpropan-2-ol was found in blood at the earliest measurement of 15 minutes after injection. Also after a single subcutaneous injection, no TBHP but mainly 2-methylpropan-2-ol was found in blood and tissues at the earliest measurement of 2 hours after injection. Based on the rapid conversion of TBHP to 2-methylpropan-2-ol after IV administration, no detectable levels of TBHP will also be expected after oral, dermal and inhalatory exposure due to the slower absorption and the first pass effect in the liver after oral exposure.

Toxicokinetic of TBHP under repeated conditions of exposure has not been investigated. 2-Methylpropan-2-ol was tested for mutagenicity by the NTP in 1995 and all *in vitro* and *in vivo* results were negative.

TBHP may undergo a one-electron oxidation generating the peroxyl radical (t-BuO $\cdot$ ) or a one-electron reduction generating the tert-butoxyl radical (t-BuO $\cdot$ ), the latter being the major process (Davies, 1988). Subsequent fragmentation of the tert-butoxyl radical results in the formation of carbon-centred radicals (CH $_3$ ; Greenley and Davies, 1992). The generation of such radicals has been demonstrated in several  $in\ vitro$  systems, such as human endothelial cells (O'Donnell and Burkitt, 1994), intact skin samples of the mouse (Timmins and Davis, 1993), rat liver microsomes (Greenley and Davies, 1992), and isolated rat liver nuclei (Greenley and Davies, 1994).

*In vivo*, an increase in free radicals was observed by Ritchie *et al.* (2005a) in the liver, kidney and blood, but not in heart or lung, after a 12-day oral exposure to 175 mg/kg, but not after dermal exposure at the same dose (Ritchie *et al.*, 2005c).

The mutagenic effects of TBHP are probably due to the formation of TBHP-derived radicals after one-electron oxidation or one-electron reduction and their reaction with DNA.

Hazlewood and Davies (1995) showed with the technique of electronic paramagnetic resonance (EPR) spin trapping that the tert-butoxyl radical generated from TBHP is capable of damaging DNA and RNA *in vitro*.

Radicals formation and their reaction with DNA will also probably depend on the antioxidant level on cells and is expected to increase at TBHP levels which induce a reduction in the antioxidant levels but formation of free radicals before antioxidant depletion cannot be excluded.

It is noted that DTBP has structural similarities with TBHP and was classified Muta 2 - H341 in a

RAC opinion of 2010 based on the following dataset: DTBP has been found to give negative results for mutagenicity *in vitro* in bacteria. Its potential to damage chromosomes or induce gene mutations in mammalian cells *in vitro* has not been studied. In two well-conducted mouse bone marrow micronucleus tests, DTBP has given clear positive results. The only available germ cell test (for chromosome aberrations in spermatogonial cells of IP treated mice) was negative.

It is assumed that the mutagenicity of DTBP is caused via the formation of radicals from DTBP. Radical formation from DTBP can occur by splitting the electronic bond between the two oxygen atoms or by splitting the bond between one oxygen atom and the carbon atom. The same radicals plus other radicals can be formed from TBHP (see figure below). Due to the substitution of both oxygens of the peroxide function, DTBP is however expected to be more stable than TBHP.

A difference in solubility was also noted during public consultation and the following water solubilities are given in the respective CLH reports: TBHP is water soluble ( $\geq$  100 g/L at 20°C) whereas DTBP is weakly soluble (0.1 g/L at 20°C).

#### Assessment and comparison with the classification criteria

No human data are available and classification as Muta 1A is therefore not appropriate.

Positive results from *in vivo* heritable germ cell mutagenicity tests in mammals are available for TBHP from studies of good quality. These positive results were obtained by the IP route. In the absence of evidence of mutagenicity of TBHP on germ cells by a physiological route of exposure, these data are therefore considered to be insufficient to warrant classification as Muta. 1B.

Negative results are obtained in *in vivo* mutagenicity tests on somatic cells located at a distance from the site of exposure after single exposure. In some of these studies, signs of effects in the tested organs were noted at the highest doses but toxicokinetic data after single exposure shows that TBHP is rapidly metabolized to the non-genotoxic 2-methylpropan-2-ol whereas DNA-reactive radicals are expected to be formed from the parent TBHP. Therefore, the reactive TBHP may not reach the tested systemic organs. The negative results for systemic genotoxicity in somatic cell after single exposure therefore does not exclude a potential for mutagenicity of TBHP after repeated exposure when metabolism is saturated and antioxidant defenses are depleted, as well as for local mutagenicity as supported by the largely positive *in* 

vitro database in absence of metabolic activation.

The *in vivo* evidence for local mutagenicity is further provided by the induction of dominant lethal mutations in germ cells by the IP route, where TBHP can migrate from the abdominal cavity through the inguinal canal to the testis. The four conclusive studies available were all performed in the same research laboratory and appear to have been designed with no major deficiencies. The results of induction of inheritable mutations were repeated and supported by the concurrent observation of oxidative stress and DNA damage in sperm cells. The relevance of the findings on germ cells for local effects in somatic cells is supported by the positive results of *in vitro* tests that were performed on somatic mammalian cells.

Local genotoxicity was directly investigated in a Comet assay with 5-day inhalation exposure in lung tissues and gave a negative result. However, the significance of this result was questioned by the lower exposure that is expected in the lower parts of the respiratory tract. The investigation of nasal and tracheal epithelium that receive a higher exposure, as evidenced by the histopathological effects observed in these tissues, was not possible due to methodological difficulties. This negative Comet result in the lung is therefore not considered sufficient to rule out the local mutagenicity of TBHP as evidenced by mutagenicity on germ cell by IP exposure that justifies a classification as Muta. 2.

It is also noted that most of the negative tests performed on somatic cells were performed with a single exposure whereas positive results on germ cells were obtained with repeated exposure. Only a bone marrow chromosomal aberration assay was performed with a 5-day exposure by inhalation (Ben-Dyke, 1981) but toxicokinetics data via this route are lacking, and it is hence not possible to conclude on exposure of the bone marrow to the reactive TBHP under these exposure conditions.

Toxicokinetic data indicates that TBHP is not likely to be systemically available and in particular not to reach germ cells after single exposure via a physiological route of exposure. However, the toxicokinetics of TBHP under repeated conditions of exposure, when metabolism is saturated and antioxidant defenses are depleted, has not been investigated. In addition, the formation of free radicals has been observed in the liver, kidney and blood after repeated exposure to TBHP by gavage (Ritchie, 2005a). Although insufficient to conclude on genotoxicity, it gives an indication that TBHP may induce oxidative damage at distant sites after repeated exposure by a physiological route.

Therefore, the potential for systemic genotoxicity of TBHP after repeated exposure cannot be fully excluded. Similarly, the absence of mutagenicity of TBHP in germ cells by a physiological route in particular under repeated exposure has not been demonstrated and the concern raised by the positive dominant lethal assays by IP route cannot be ruled out with certainty. This is considered as a supportive element to warrant a classification as Muta. 2.

It is also noted that the substance DTBP shares with TBHP the formation of the same reactive radicals. DTBP is genotoxic in somatic cells at distant sites, which brings some support to the mutagenic effect of TBHP. Some differences between the two substances are noted: difference in water solubility, expected higher stability of DTBP, possibility to form additional radicals (more reactive) from TBHP. These differences may explain the difference in the *in vitro* results (negative for the more stable DTBP) as well in the *in vivo* results (negative at distant sites for unstable TBHP). However, the explanations of the differences in the mutagenic profile between the two substances remains speculative and, although not contradictory, data on DBTP are considered of limited use to conclude on the mutagenic classification of TBHP.

Overall, RAC concludes that a classification of TBHP as Muta. 2; H341 is warranted based on the evidence of mutagenic potential provided by the available positive *in vitro* studies and the reproducible positive results reported in dominant lethal mutation assays performed by the intra-peritoneal route.

These studies show evidence for local, site of initial contact mutagenicity of TBHP, and as such are not contradicted entirely by the available negative results in studies for genetic toxicity in the liver and bone marrow. Besides, there remains a potential that repeated high dose exposure to TBHP could lead to a saturation of its primary metabolism and the depletion of anti-oxidant defences systemically in target tissues. This has not been tested experimentally. As such, the possibility of a mutagenic potential on germ cells and somatic cells at distance sites cannot be fully excluded, in particular after repeated exposure.

ECBI/03/06 Add. 8 NL, response to comments to C&L proposal

ECBI/87/06 F, Comment

**The Chair** introduced the classification proposal from NL, and mentioned the comments from D and F received prior the meeting.

**NL** said that the first issue to discuss was the actual name of the substance since it was mentioned in a comment that the substance containing less than 30% of water should also be classified as explosive. However, the substance was not marketed in such a form. The TC C&L agreed that the

substance will be covered in a single entry namely "Tert-butyl hydroperoxide (containing > 30% water)".

The TC C&L then agreed to classify TBHP with O; R7 and R10 and to apply also S43

**IND** asked whether in regard to inhalational toxicity the values obtained should be re-calculate to 100% of the substance **NL** answered that that was not necessary since it was the vapour that was tested. **IND** after reflecting agreed to the proposed classification with T; R23 that was then agreed by the TC C&L.

Also Xn; R21-22 and R34 and the application of R37 with SCLs at 10 % were agreed by **the TC C&L**.

**NL** reported that there was a negative Buehler test and a positive GPMT. Thus they proposed R43 and based on the potency considerations also SCLs with  $C \ge 0.1\%$  (instead of the 1% default value).

**UK** and **B** said that they were not so sure to support specific concentration limits as suggested by the NL. **UK** also stressed that the guidance document for potency of sensitisation (which was employed by when proposing SCLs the NL) had not formally been adopted by the TC C&L. **D** did not agree to the application of SCLs. While the GMPT indicated a borderline effect up to strong sensitization the Buehler test was negative. **NL** responded to that saying that in the expert report (draft guidance) it was clearly stated that in case of differing results from different tests the most severe result should be used.

**The Chair** then asked all other MS to give their opinion on the issue and a majority agreed to the application of SCLs for R43 as proposed by NL.

**NL** further went on saying that while for repeat dose effects there was no classification warranted based on data there were clearly positive in vitro mutagenicity tests available. *In vivo* the results were mainly negative. Thus **NL** suggested Muta. Cat. 3; R68. **D**, however, was of the opinion that the *in vivo* data did not support a classification for mutagenicity. **F** and **UK** agreed to Muta. Cat. 3; R68 adding that possibly the in vivo test were negative because of the site where the substance was applied. There was a data gap regarding *in vivo* mutagenicity tests. The in vivo tests were done with high doses. A test with skin application of the substance to the skin would have to be done in order to get a clear picture. After an extensive summary given by **IND** on the mutagenicity database and the reasons for their proposal not to classify TBHP for mutagenicity (their arguments can be found in ECBI/03/06 Add. 2) the **Chair** asked all MS to give their opinion on the issue and a majority agreed to the application of Muta. Cat. 3; R68. **UK** suggested because of the split opinions on that matter to give the TC C&L further possibility to reflect on the issue. Following that suggestion the

Chair stated that the recommendation taken was only provisional and that it was still possible to come back to the issue within the follow-up period.

The TC C&L furthermore agreed without discussion to follow the NL proposals not to classify for carcinogenicity (based on lack of data), fertility and development.

## **Conclusion:**

The TC C&L agreed that the name of the substance should be "TBHP in 30% water" and that a splitting of entries (suggested by DE) was not necessary since the substance was marketed only in this form.

Although a majority of the TC C&L agreed to apply Muta. Cat. 3; R68 the recommendation is only provisional in order to give MS the time to reflect further on the issue within the follow up period.

## **Follow-up:**

**BE** sent in a written comment where they favoured no classification for mutagenicity. NL in response to that submitted document ECBI/03/06 Add. 9 (still supporting Muta Cat. 3 R68). **DE** reiterated also their position.**UK** suggested further discussion of the issue. It was concluded to rediscuss mutagenicity at the meeting in March 2006.

N; R51-53

0406

*In October 2006* the substance was discussed for the first time based on the NL proposal. NL had sent in a second revision of their C&L proposal (ECBI/03/06 Rev.2) and reactions to the written comments received during the preparation period in ECBI/03/06 Add. 8.

At the meeting in October 2006 the TC C&L agreed that the name of the substance should be "TBHP in 30% water" and that a splitting of entries (suggested by D) was not necessary since the substance was marketed only in this form.

Although a majority of the TC C&L agreed to apply Muta. Cat. 3; R68 the recommendation is only provisional in order to give MS the time to reflect further on the issue within the follow up period.

All other endpoints were agreed as proposed by the NL rapporteur.

Member States not agreeing to Muta. Cat. 3; R68 were asked to react during Follow-up period else the provisionally classification will be regarded as a final classification proposal from the TC C&L.

**BE** did not support classification with R68 because, typically the substance is only a local mutagen and not a systemic mutagen. It is not the first time we have such a case: for example, the pesticide dichlorvos is also a local mutagen and not a systemic mutagen and it is not classified for mutagenicity. Could it be possible to raise the question in the pesticide group (meeting November)? It seems us very important to have the same approach in the two groups when classifying substances to avoid any inconsistency.

**NL** responded to the BE comment in document ECBI/03/06 Add. 9

The **DE** position for not to classify with R68 is still the same and was explained in written before.

Xi; R37: 5% ≤ C < 10% Agreed 1006

R43: C ≥ 0.1% Agreed 1006

## **Labelling:**

O, T, N

R: 7-10-21/22-23-34-43-68-5051/53

# Classification assigned in accordance with the CLP Regulation:

Org. Perox. EF; H242

Flam. Liq. 3; H226

Muta. 2; H341

Acute Tox. 2; H330

Acute Tox. 3; H311

Acute Tox. 4; H302

Skin Corr. 1C; H314

Skin Sens. 1; H317

Eye dam. 1; H318

Aquatic Chronic 2; H411

## **Specific concentration limits:**

Skin Sens. 1; H317: C ≥ 0.1%

(Xi; R37:  $5\% \le C < 10\%$ ] Translation of this SCL not necessary as the new GCL for Corrosive substances is 5 %.) UK agreed with BE that it is important to ensure consistency in classification in these cases. TBHP is an in vitro mutagen but has tested negative in standard in vivo tests. The concern, leading to R68, was that because of the reactivity of TBHP these negative findings may be a false negative due to insufficient exposure of the tissues examined (bone marrow) and TBHP might still be a mutagen at the local site of contact (e.g. in the lungs following inhalation or skin) and given that local mutagenicity has not been investigated this is a remaining concern. It may be appropriate to have a discussion on the general issue of how such substances should be classified for mutagenicity.

**NL** sent a revised proposal for TBHP, including the GHS classification in document ECBI/03/06 Rev. 3. The rationale for the presented GHS classification can be found there. In addition NL proposes to use STOT 1 or 2 for "Corrosive to the respiratory tract".

Furthermore NL confirmed that the GHS classification should be Org. Perox. EF for O; R7.

**DK** sent their position in support of classification mutagenicity in document ECBI/03/06 Add. 10 distributed with Rev. 2 of the September agenda. In addition they suggest classifying with Carc. Cat. 3; R40.

**Conclusion Follow-up:** Based on the comments by BE, DK, DE and UK, mutagenicity should be re-discussed at the September 2007 meeting.

MS were invited to send further comments/positions within the deadlines for the September meeting to facilitate the discussions. In addition MS were asked to react in written prior the meeting in case they supported to further discuss carcinogenicity as suggested by DK.

There was no additional support for further discussion of carcinogenity.

NL presented their position on mutagenicity and carcinogenicity together with a summary of new studies in document ECBI/03/06 Add. 11 distributed with Revision 5 of the agenda. They support Muta.Cat.3; R68 (and Muta. 2 H341) and state that the data available is insufficient for classification for carcinogenicity.

In September 2007 the TC C&L agreed to confirm the provisional classification for Muta. Cat. 3; R68 (Muta. 2 H341) from the last meeting, and not to classify with STOT 1 or 2 under the CLP Regulation as the

effects were already covered by the agreed classification.

NL: There is a difference in the follow-up document I for the environmental classification between the classification and the labelling. Could you please check this? Does this affect the S-sentences? ECB: Yes, thanks this is correct. It should be R51-53 and S61.
